## 1.0 DESCRIPTION OF THE ACTIVITY

### 1.1 Introduction

On May 7, 2007, the National Marine Fisheries Service (NOAA Fisheries) issued to Northeast Gateway<sup>®</sup> Energy Bridge<sup>™</sup>, L.P. (Northeast Gateway<sup>®</sup>) and Algonquin Gas Transmission, L.L.C. (Algonquin) an Incidental Harassment Authorization (IHA) pursuant to Section 101(a)(5) of the Marine Mammal Protection Act (MMPA) and 50 Code of Federal Regulations (CFR) § 216 Subpart I to allow for the incidental harassment of small numbers of marine mammals resulting from the construction and operation of the Northeast Gateway Deepwater Port (NEG Port or Port) and the Algonquin Pipeline Lateral (Pipeline Lateral). The regulations set forth in Section 101(a)(5) of the MMPA and 50 CFR § 216 Subpart I allows for the incidental taking of marine mammals by a specific activity if the activity is found to have a negligible impact on the species or stock(s) of marine mammals and will not result in immitigable adverse impact on the availability of the marine mammal species or stock(s) for certain subsistence uses. Per this regulation, Level B take for incidental harassment was granted to Northeast Gateway and Algonquin for the North Atlantic right whale (*Eubalaena glacialis*), humpback whale (*Megaptera novaeangliae*), fin whale (*Balaenoptera physalus*), minke whale (*Balaenoptera acutorostrata*), pilot whale (*Globicephala* spp.), Atlantic white-sided dolphin (*Lagenorhynchus acutus*), common dolphin (*Delphinus delphis*), harbor porpoise (*Phocoena phocoena*), harbor seal (*Phocac vitulina*), and gray seal (*Halichoerus grypus*). This authorization was amended on November 30, 2007 and has been subsequently renewed on May 15, 2008, August 28, 2009, August 27, 2010 and October 6, 2011.

In support of continued Port operations, Northeast Gateway is petitioning NOAA Fisheries for the renewal of its IHA as issued on October 6, 2011 which expired on October 5, 2012. Per the recommendation of the National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NOAA Fisheries), Northeast Gateway and Algonquin have prepared this request for the taking by harassment, of small numbers of marine mammals in Massachusetts Bay, to be valid for a period of one (1) year from the date of authorization. Northeast Gateway has based this request on take calculations conducted for the NEG Port operational activities, as was provided by the October 6, 2011 IHA. NEG Port maintenance and repair activities have been calculated based on site-specific acoustic data collected during Port construction. In addition, Algonquin has calculated potential take for maintenance and repair activities for the Pipeline Lateral based on the same site-specific acoustic data. The following sections further describe the NEG Port and Algonquin Pipeline Lateral and the operational and repair/maintenance activities that could result in the potential take, by Level B harassment, of marine mammals under the MMPA. This is consistent with the direction of NOAA Fisheries provided on February 23, 2011 via personal communication with Shane Guan.

### 1.2 Northeast Gateway Deepwater Port and Algonquin Pipeline Lateral

The NEG Port is located in Massachusetts Bay and consists of a submerged buoy system to dock specially designed liquid natural gas (LNG) carriers approximately 13 miles (21 kilometers) offshore of Massachusetts in federal waters approximately 270 to 290 feet (82 to 88 meters) in depth. This facility delivers regasified LNG to onshore markets via the Algonquin Pipeline Lateral. The Pipeline Lateral consists of a 16.1-mile (25.8-kilometer) long, 24-inch (61-centimeter) outside diameter natural gas pipeline which interconnects the Port to an offshore natural gas pipeline known as the HubLine<sup>1</sup>.

---

<sup>1</sup> HubLine is an existing 30-inch-diameter interstate natural gas pipeline that was constructed by Algonquin in 2002/2003. HubLine starts at its connection with the Maritimes & Northeast Pipeline, L.L.C. Phase III Pipeline in

The NEG Port consists of two subsea Submerged Turret Loading™ (STL<sup>2</sup>) buoys, each with a flexible riser assembly and a manifold connecting the riser assembly, via an 18-inch diameter subsea Flowline, to the Pipeline Lateral. Northeast Gateway utilizes vessels from its current fleet of specially designed Energy Bridge™ Regasification Vessels (EBRVs<sup>®3</sup>), each capable of transporting approximately 2.9 billion cubic feet (82 million cubic meters) of natural gas condensed to 4.9 million cubic feet (138,000 cubic meters) of LNG. Northeast Gateway has recently added two vessels to its fleet that have a cargo capacity of approximately 151,000 cubic meters of LNG. The mooring system installed at the NEG Port is designed to handle each class of vessel. The EBRVs will dock to the STL buoys, which will serve as both the single-point mooring system for the vessels and the delivery conduit for natural gas. Each of the STL buoys is secured to the seafloor using a series of suction anchors and a combination of chain/cable anchor lines.

On June 13, 2005, Northeast Gateway submitted an application to the U.S. Coast Guard (USCG) and the Maritime Administration (MARAD) seeking a federal license under the Deepwater Port Act to own, construct, and operate a deepwater port for the import and regasification of LNG in Massachusetts Bay, off the coast of Massachusetts. The Northeast Gateway application was assigned Docket Number USCG-2005-22219. Simultaneous with this filing, Algonquin, now a subsidiary of Spectra Energy Corp, filed a Natural Gas Act Section 7(c) application with the Federal Energy Regulatory Commission (FERC) for a Certificate of Public Convenience and Necessity (Certificate) for the Pipeline Lateral that would connect the NEG Port with the existing HubLine natural gas pipeline for transmission throughout New England (FERC Docket Number CP05-383-000).

The USCG, in coordination with the FERC, published a Final Environmental Impact Statement/Environmental Impact Report (final EIS/EIR) for the proposed NEG Port and Algonquin Pipeline Lateral on October 27, 2006. This document provides detailed information on the NEG Port and Pipeline Lateral, operations methods, and analysis of potential impacts on marine mammals as well as other environmental resources.

On May 14, 2007, MARAD issued a license to Northeast Gateway to own, construct, and operate a deepwater port. The FERC issued its Certificate to Algonquin on March 16, 2007. Construction of the NEG Port and Algonquin Pipeline Lateral was completed in December 2007, and the Port was commissioned for operation by the USCG in February 2008.

### **1.3 NEG Port and Algonquin Pipeline Lateral Operation and Maintenance Activities**

#### **1.3.1 NEG Port**

This section describes the operation and maintenance (O&M) activities that are required for the NEG Port. NEG Port O&M activities will be completed in accordance with the Classification Society Rules (American Bureau of Shipping). NEG Port Flowlines' O&M activities will be performed in accordance with U.S. Department of Transportation (DOT) regulations (49 CFR Part 192).

<sup>3</sup> EBRV is a trademark of Northeast Gateway, L.P.

### *1.3.1.1 NEG Port Operations*

During NEG Port operations, EBRVs servicing the NEG Port shall utilize the International Maritime Organization (IMO)-approved Boston Traffic Separation Scheme (TSS) on their approach to and departure from the NEG Port at the earliest practicable point of transit. EBRVs shall maintain speeds of 12 knots or less while in the TSS unless transiting the Off Race Point Seasonal Management Area between the dates of March 1 and April 30, the Great South Channel Seasonal Management Area between the dates of April 1 and July 31, or when there have been active right whale sightings<sup>4</sup>, active acoustic<sup>5</sup> detections, or both, in the vicinity of the transiting EBRV in the TSS or at the NEG Port whereby the vessels must slow their speeds to 10 knots or less. Appendix A contains the National Oceanic and Atmospheric Administration (NOAA)-approved Marine Mammal Detection, Monitoring, and Response Plan for Operation of the Northeast Gateway Energy Bridge Deepwater Port and Algonquin Pipeline Lateral, which describes in detail the measures required for EBRVs transiting in the TSS or within the NEG Port area.

As an EBRV makes its final approach to the NEG Port, vessel speed will gradually be reduced to 3 knots at 1.86 miles (2.99 kilometers) out to less than 1 knot at a distance of 1,640 feet (500 meters) from the NEG Port. When an EBRV arrives at the NEG Port, it will retrieve one of the two permanently anchored submerged STL buoys. It will make final connection to the buoy through a series of engine and bow thruster actions. The EBRV will require the use of thrusters for dynamic positioning during docking procedure. Typically, the docking procedure is completed over a 10- to 30-minute period, with the thrusters activated as necessary for short periods (bursts in seconds), not a continuous sound source. Once connected to the buoy, the EBRV will make ready to begin vaporizing the LNG into its natural gas state using the onboard regasification system. As the LNG is regasified, natural gas will be transferred at pipeline pressures off the EBRV through the STL buoy and flexible riser via a steel flowline leading to the connecting Algonquin Pipeline Lateral. When the LNG vessel is on the buoy, wind and current effects on the vessel will be allowed to “weathervane” on the single-point mooring system; therefore, thrusters will not be used to maintain a stationary position.

It is estimated that the NEG Port could receive approximately 65 cargo deliveries a year. During this time period thrusters will be engaged in use for docking at the NEG Port approximately 10 to 30 minutes for each vessel arrival and departure.

### *1.3.1.2 NEG Port Maintenance and Repair*

The specified design life of the NEG Port is about 40 years, with the exception of the anchors, mooring chain/rope, and riser/umbilical assemblies, which are based on a maintenance-free design life of 20 years. The buoy pick-up system components are considered consumable and are inspected following each buoy connection, and replaced (from inside the STL compartment during the normal cargo discharge period) as deemed necessary. The underwater components of the NEG Port are inspected once yearly in accordance with Classification Society Rules (American Bureau of Shipping) using either divers or remotely operated vehicles (ROV) to inspect and record the condition of the various STL system components. These

---

<sup>4</sup> Active right whale sightings are all right whale sightings broadcast by the Mandatory Ship Reporting or Sighting Advisory System.

<sup>5</sup> Active acoustic detections are confirmed right whale vocalizations detected by a TSS auto-detection buoy (AB) within 24 hours of each scheduled data review period (e.g., every 30 minutes or every 12 hours, as detailed in subsequent text). Multiple confirmed acoustic detections at a single AB will extend the duration of minimum mandated LNGRV response to 24 hours from the last confirmed detection (within the reception area of the detecting AB). Confirmed acoustic detections at multiple ABs within the same 24-hour period will extend the area of minimum mandated LNGRV response to encompass the reception areas of all detecting ABs.

activities are conducted using the NEG Port's normal support vessel (125-foot [38 meter], 99 gross ton, 2,700 horsepower, aluminum mono-hull vessel), and to the extent possible coincide with planned weekly visits to the NEG Port. Helicopters will not be used for marker line maintenance inspections.

In addition to these routine activities, there may be instances whereby unanticipated events at the NEG Port necessitate emergency maintenance and/or repair activities. While the extent and number of such maintenance and repair activities at the NEG Port over its expected 25 year life cannot be accurately estimated, it is reasonable to assume that a worst-case maintenance and/or repair scenario would result in similar types of activities and require the use of similar support vessels and equipment as used for construction. There may also be certain unanticipated circumstances that require the presence of an EBRV at the NEG Port to support these maintenance and repair activities (e.g., maintenance and repair on the STL Buoy, vessel commissioning, and any onboard equipment malfunction or failure occurring while a vessel is present for cargo delivery). Potential noise effects would be associated with underwater acoustic harassment of marine mammals and sea turtles from the use of thrusters during mooring and unmooring as described for NEG Port operations. Mitigation and monitoring strategies are already in place to mitigate for such effects when EBRVs are transiting within the designated TSS, transiting to the Broad Sound Anchorage area, maneuvering within the Port's Area to be Avoided, transiting between Port Buoys, and/or while actively engaging in the use of thrusters. Therefore, acoustic impacts associated with unanticipated EBRV-supported maintenance and/or repair activities at the Port under the Proposed Action would be the same as those described for NEG Port operations. Additionally, as published in the Federal Register (Vol. 76, No. 113), the NOAA Fisheries determined that the evaluation of a 14-day maintenance period was appropriate for evaluating the potential take associated with a maintenance and repair at the Neptune Port Facility. Due to the fact that both the NEG and Neptune Ports are very similar in their potential need and type of maintenance and repair of port facilities, we have applied the same average duration of 14 days to complete NEG Port maintenance and repair activities.

### **1.3.2 Algonquin Pipeline Lateral O&M Activities**

This section describes the operation and maintenance (O&M) activities that are required for the Algonquin Pipeline Lateral. The Algonquin Pipeline Lateral O&M activities will be performed in accordance with U.S. Department of Transportation (DOT) regulations (49 CFR Part 192). The O&M activities associated with the Algonquin Pipeline Lateral can be subdivided into two categories, Routine O&M Activities and Unplanned Repair Work. Routine operation of the Algonquin Pipeline Lateral will not result in the potential take, by Level B harassment, of marine mammals under the MMPA. While the 0.7 and 0.51-mile (1.13 and 0.82- kilometer) Flowlines are part of the NEG Port, because of their similar functions and requirements, for the purposes of this application and subsequent authorization, they will be considered as part of the Algonquin Pipeline Lateral activities.

#### **1.3.2.1 Routine O&M Activities**

The planned activities required for the O&M of the Algonquin Pipeline Lateral and Flowlines over a 1-year period are limited. Similar to the inspection of the NEG Port underwater components, the only planned O&M activity is the annual inspection of the cathodic protection monitors by a ROV. The monitors are located at the ends of the Algonquin Pipeline Lateral and the adjacent Flowlines. Each inspection activity will take approximately 3 days and will utilize a ROV launched from a vessel of opportunity. The most likely vessel will be similar to the NEG Port's normal support vessel referenced in section 1.3.1.2. This vessel is self-positioning and requires no anchors or use of thrusters. No forms of take by the operation of this vessel are likely or anticipated. The requested take authorization would apply to Algonquin Pipeline Lateral activities described regardless of the individual actor (e.g., vessel owner,

operator, contractor, etc.) provided that the conditions of the take authorization are met. The vessel will mobilize from Salem, Massachusetts and will inspect the monitors in the vicinity of the NEG Port and at the point where the Algonquin Pipeline Lateral interconnects with Algonquin's HubLine. These activities will be performed during daylight hours and during periods of good weather.

### *1.3.2.2 Unplanned Pipeline Repair Activities*

Unplanned O&M activities may be required from time to time at a location along the Algonquin Pipeline Lateral or along one of the Flowlines should the line become damaged or malfunction. Repair activities requiring limited excavation to access the pipeline or cathodic protection maintenance are authorized by the FERC certificate.

Should repair work be required, it is likely a dive vessel would be the main vessel used to support the repair work. The type of diving spread and the corresponding vessel needed to support the spread would be dictated by the type of repair work required and the water depth at the work location. In addition, the type of vessel used may vary depending upon availability. The duration of an unplanned activity would also vary depending upon the repair work involved (e.g., repairing or replacing a section of the pipeline, connection, or valve) but can generally be assumed to take less than 40 work days to complete based on industry experience with underwater pipeline repairs.

A diving spread required to execute an unplanned activity might necessitate several vessels. Most likely the dive vessel would support a saturation diving spread and be moored at the work location using four anchors. This vessel would transit to and from the location in accordance with the conditions stated in the Marine Mammal Detection, Monitoring, and Response Plan (MMDMRP) for Operation, Maintenance and Repair of the Northeast Gateway Energy Bridge Deepwater Port and Algonquin Pipeline Lateral (see Appendix A) and would likely be accompanied by an attendant tug to assist with anchor placement. Once secured at the work location, the dive vessel would remain on site through the completion of the work, weather permitting. A crew/supply boat would be utilized to intermittently provide labor and supply transfers. Once or twice during the work, a tug may be required to bring a material barge to and from the location. While unlikely, there is a small possibility that a second dive vessel would be required to support the main dive vessel, depending upon the work activity. The second dive vessel would be on-site for a shorter work duration. As discussed in more detail in section 13.0 and in Appendix A, the crews would be provided with project-specific training on the requirements for monitoring and reacting to the sighting of marine mammals and/or sea turtles. These vessels would be supported from an onshore base located between Quincy, Massachusetts and Gloucester, Massachusetts.

The selection of a dive vessel will be driven by the technical requirements of the work. In addition, the degree of urgency required to address the work and the availability of vessels will also enter into the decision process for securing a dive vessel. It may be that a four-point moored dive vessel is either not available or doesn't meet the technical capabilities required by the work. It then becomes possible that a dynamically positioned (DP) dive vessel may have to be utilized. The use of a DP dive vessel removes the need for an attendant tug to support the vessel since no anchors will be deployed. However, potential impacts related to noise are increased when a DP dive vessel is used. The noise generated by a DP dive vessel varies, and results from the use of the thrusters which run at various levels to maintain the vessel's position during the work depending upon currents, winds, waves and other forces acting on the vessel at the time of the work.

## 1.4 NEG Port and Algonquin Pipeline Lateral Activities Resulting in the Potential Incidental Taking of Marine Mammals

Under the 1994 Amendments to the MMPA, NOAA Fisheries defines the zone of injury as the range of received levels from 180 linear decibels (dBL) referenced to 1 microPascal ( $\mu\text{Pa}$ ) root mean square (RMS) (180 dBL re 1  $\mu\text{Pa}$ ), for mysticetes and odontocetes, and 190 dBL re 1 $\mu\text{Pa}$  for and pinnipeds. This ruling was made in relation to a permit for seismic surveys in offshore waters (NOAA 1995); the guidance was subsequently updated to include all odontocetes within the 180 dB re 1 $\mu\text{Pa}$  sound exposure limit (NOAA 1999). This threshold considers instantaneous sound pressure levels at a given receiver location. The NOAA Fisheries 180 dBL re 1  $\mu\text{Pa}$  guidelines are designed to protect all marine species from high sound pressure levels at any discrete frequency across the entire frequency spectrum. It is a very conservative criterion as it does not consider species-specific hearing capabilities.

The MMPA defines Level B harassment as any act of pursuit, torment, or annoyance that has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. NOAA Fisheries defines the threshold level for Level B harassment at 160 dBL re 1 $\mu\text{Pa}$  for impulsive sound, averaged over the duration of the signal. A summary of the NOAA Fisheries cause and effect noise criteria are summarized in Table 1-1.

**Table 1-1. Summary of NOAA Fisheries Cause and Effect Noise Criteria (NOAA 2005)**

	Criteria Level	Type
Level A Harassment	180 dBL re 1 $\mu\text{Pa}$ (RMS)	Absolute
Level B Harassment	160 re 1 $\mu\text{Pa}$ (RMS)	Impulse
	120 re 1 $\mu\text{Pa}$ (RMS)	Continuous

Regulatory criteria for marine mammals were revised by NOAA as part of a ruling on a permit application for a military sonar exercise (NOAA 2006). These criteria establish thresholds at which temporary or permanent hearing loss is expected for marine mammals. A temporary or reversible elevation in hearing threshold is termed a temporary threshold shift (TTS), while a permanent or unrecoverable reduction in hearing sensitivity is termed a permanent threshold shift (PTS). NOAA (2006) established a TTS of 195 dB re 1  $\mu\text{Pa}^2\text{-s}$  and a PTS of 215 dB 1  $\mu\text{Pa}^2\text{-s}$  for marine mammals based on the typical values for the additional dB above TTS required to induce PTS in experiments with terrestrial mammals. The revised TTS and PTS thresholds are defined as an energy flux density (EFD), which is the acoustic energy passing through a particular point per-unit decibel; therefore, TTS and PTS are given in the units of dB re 1 $\mu\text{Pa}^2\text{-s}$ , the integration of RMS sound pressure over a one second duration. Being time energy based, the TTS and PTS thresholds take into account cumulative sound exposure.

Activities that could result in the incidental take of marine mammals are limited to the generation by vessels of underwater noise that has the potential to cause Level B harassment as defined by the MMPA. No other operation and maintenance activities as described in sections 1.3.1 and 1.3.2 are likely to result in the take of marine mammals.

Northeast Gateway contracted with Tetra Tech EC, Inc. (Tetra Tech) to perform field investigations to document underwater noise levels emitted during the construction of the NEG Port and Algonquin Pipeline Lateral and during the operation of NEG Port facilities (namely the operation of EBRVs). Tetra

Tech conducted five offshore hydroacoustic field programs: one in 2005 and one in 2006 at the Gulf Gateway Deepwater Port located approximately 116 miles off the coast of Louisiana in the Gulf of Mexico; and three in 2007 at the NEG Port and Algonquin Pipeline Lateral Project area (see Table 1-2). The 2005 measurements were completed to determine underwater noise levels during EBRV onboard regasification and vessel movements. The data from the 2005 field program was used to support the modeling and analysis of potential acoustic affects of EBRV operations in Massachusetts Bay during the NEG Port permitting and licensing process. The data collected in 2006 was also associated with EBRV operation activities and were collected for the purpose of verifying the measurement completed in 2005 as well as to further document sound levels during additional operational and EBRV activities such as EBRV coupling and decoupling from the buoy system, transit and the use of stern and bow thrusters required for dynamic positioning. The 2007 measurements were collected during NEG Port and Algonquin Pipeline Lateral construction to obtain site-specific underwater sound-level data associated with various construction activities that were previously modeled in support of permitting and licensing.

**Table 1-2. Chronological Timeline**

03/20-24/05	Gulf of Mexico Deployment	Operation
08/03-04/06	Gulf of Mexico Deployment	Operation
06/27/07	Massachusetts Bay Deployment 1	Construction – Pipe lay
08/01/07	Massachusetts Bay Deployment 2	Construction - Plowing
08/27/07	Massachusetts Bay Deployment 3	Construction - Backfilling

A detailed report describing both the 2006 and 2007 operation and construction noise measurement events and associated results have been included as Appendix B. Activities that could result in the incidental take of marine mammals are limited to the generation by vessels of underwater noise that has the potential to cause Level B harassment as defined by the MMPA. The following sections describe those activities that could result in Level B harassment as they relate to NEG Port and Algonquin O&M activities.

## **1.4.1 NEG Port**

### **1.4.1.1 NEG Port Operations**

For the purposes of understanding the noise footprint of operations at the NEG Port, measurements taken to capture operational noise (docking, undocking, regasification, and EBRV thruster use) during the 2006 Gulf of Mexico field event were taken at the source. Measurements taken during EBRV transit were normalized to a distance of 328 feet (100 meters) to serve as a basis for modeling sound propagation at the NEG Port site in Massachusetts Bay.

Sound propagation calculations for operational activities were then completed at two positions in Massachusetts Bay to determine site-specific distances to the 120/160/180 dB isopleths:

- Operations Position 1 - Port (EBRV Operations): 70° 36.261' W and 42° 23.790' N
- Operations Position 2 – Boston TSS (EBRV Transit): 70° 17.621' W and 42° 17.539' N

At each of these locations sound propagation calculations were performed to determine the noise footprint of the operation activity at each of the specified locations. Calculations were performed in accordance with Marsh and Schulkin (1985) and Richardson et al (1995) and took into consideration aspects of water depth, sea state, bathymetry, and seabed composition. In addition, the acoustic modeling performed specifically evaluated sound energy in 1/3-octave spectral bands covering frequencies from 12.5 hertz

(Hz) to 20 kilohertz (kHz). This range encompasses the auditory frequency range of marine mammals and the range at which sound propagates beyond the immediate vicinity of the source (i.e., high frequency sounds have a much higher attenuation rate than frequencies in the low to middle range due to a higher absorption rate by seawater and boundary effects). These results were then summed across frequencies to provide the broadband received levels at receptor locations. A literature review of relevant underwater noise measurement data of offshore construction activities in similar shallow water environments were referred to for estimating typical propagation rates.

Appendix C provides a detailed description of the propagation calculation methodologies employed. Table 1-3 provides a summary of the resultant underwater sound pressure levels and distance to the 120/160 dB isopleths by activity type and identified position. As identified in Table 1-3, none of the modeled activities were found to reach the 160 dB isopleths at any appreciable distance from the sources evaluated and the use of EBRV onboard equipment during regasification will only result in low level noise above ambient, but only for relatively short distances. It is important to note, that the results presented in Table 1-3, do not include existing acoustic underwater ambient conditions which may effectively mask project sounds at sufficient distances. To further understand how NEG Port activities may result in underwater noise that could harass marine mammals, Northeast Gateway has engaged representatives from Cornell University’s Bioacoustics Research Program (BRP) and the Woods Hole Oceanographic Institution (WHOI) as the consultants for collecting and analyzing the acoustic data throughout the project area (see sections 13.0 and 14.0). Elevated underwater sound levels within Massachusetts Bay due to this existing vessel traffic and other Bay activities may effectively mask sound generated during Port activities. Sound levels recorded by marine autonomous recording units (MARUs) within frequency bands for marine mammals have been reported to include whales, other biotic and abiotic sound sources and ambient noise that could be occurring at the time (BRP 2011).

**Table 1-3. Resultant underwater sound pressure levels and distance to threshold levels during NEG Port Operation**

	<b>Estimated Distance (meters) from source at which Sound Pressure Level falls below 160 dBL</b>	<b>Estimated Distance (meters) from source at which Sound Pressure Level falls below 120 dBL</b>
Typical EBRV docking procedure with support vessel Position 1: Port	<0.1	4250
Typical EBRV docking procedure with support vessels (2 - EBRVs on station) Position 1: Port	<0.2	5500
EBRV Regasification Position 1: Port	n/a	<300
EBRV transiting the TSS 10 knot	<0.1	1750

The resulting distances to the 120/160 dB isopleths have been conservatively estimated to determine the maximum distance at which Level B harassment may occur. Impulsive pressure levels produced by thrusters during maneuvering to and from the Port drop quickly below the 160 dB isopleth. These most recent modeling results are consistent with the final EIS/EIR which concluded that noise produced by thrusters would fall below the Level B harassment threshold within 100 meters from the source. For continuous noise produced by EBRV transit, the final EIS/EIR concluded that sound pressure levels to the

120 dB isopleth would dissipate within a zone approximately 1000 meters from the EBRV. While the latest modeling data shows an increase in distance out to the 120 dB isopleth, current mitigation and monitoring requirements to avoid and/or minimize harassment of marine mammals and sea turtles, as required by the NEG Port's MARAD/USCG License and NOAA Fisheries Biological Opinion (BO), and as assumed in previous IHAs and described in section 11.0, exceed the modeled distances.

#### *1.4.1.2 NEG Port Maintenance and Repair*

As stated in section 1.3.1.2, routine inspections of NEG Port mooring components occur after each buoy connection from the Port's normal support vessel. Inspections of other Port facility components such as the STL Buoy, flexible riser, mooring system, pipeline end manifold (PLEM) are conducted annually by a ROV and/or diver launched from a vessel of opportunity.

In addition to these routine activities, there may be instances whereby unanticipated events at the NEG Port necessitate emergency maintenance and/or repair activities. While the extent and number of such maintenance and repair activities at the NEG Port over its expected 25 year life cannot be accurately estimated, it is reasonable to assume that a worst-case maintenance and/or repair scenario would result in similar types of activities and require the use of similar support vessels and equipment as used for construction.

Modeling analysis conducted in support of the final EIS/EIR concluded that the only underwater noise of critical concern during NEG Port construction would be from vessel noises such as turning screws, engine noise, noise of operating machinery, and thruster use. To confirm these modeled results and better understand the noise footprint associated with construction activities at the NEG Port, field measurements were taken of various construction activities during the 2007 NEG Port and Algonquin Pipeline Lateral Construction period (see Table 1-1). Measurements were taken and normalized as described in section 1.4.1.1 to establish the "loudest" potential construction measurement event. One position within Massachusetts Bay was then used to determine site-specific distances to the 120/160/180 dB isopleths for NEG Port maintenance and repair activities:

- Construction Position 1. Port: 70° 36.261' W and 42° 23.790' N

As described for NEG Port operations, sound propagation calculations were performed to determine the noise footprint of the construction activity. The calculations took into consideration aspects of water depth, sea state, bathymetry, and seabed composition, and specifically evaluated sound energy in the range that encompasses the auditory frequencies of marine mammals and at which sound propagates beyond the immediate vicinity of the source. These results were then summed across frequencies to provide the broadband received levels at receptor locations. Appendix C provides a detailed description of the propagation calculation methodologies employed. Table 1-4 provides a summary of the resultant underwater sound pressure levels and distance to the 120/160 dB isopleths for NEG Port construction activity in the Port area. As identified in Table 1-4, modeled activities for barge and tug were found to reach the 160 dB isopleths at any appreciable distance from the sources evaluated. As with NEG Port operations, it is important to note that the results presented in Table 1-4, do not include existing acoustic underwater ambient conditions which may effectively mask project sounds at sufficient distances. Elevated underwater sound levels within Massachusetts Bay due to this existing vessel traffic and other Bay activities may effectively mask sound generated during Port maintenance and repair activities. Sound levels recorded by MARUs within frequency bands for marine mammals have been reported to include whales, other biotic and abiotic sound sources and ambient noise that could be occurring at the time (BRP 2011).

**Table 1-4 Resultant underwater sound pressure levels and distance to threshold levels during NEG Port Construction**

	Estimated Distance (meters) from source at which Sound Pressure Level falls below 160 dBL	Estimated Distance (meters) from source at which Sound Pressure Level falls below 120 dBL
<b>NEG Port: Construction</b>		
Barge / Tug (pulling and pushing) / Construction Vessel / Barge Position 1: Port	n/a	2560

The resulting distances to the 120/160 dB isopleths have been conservatively estimated to determine the maximum distance at which Level B harassment may occur. While the latest modeling data shows an increase in distance out to the 120 dB isopleth, current mitigation and monitoring requirements to avoid and/or minimize harassment of marine mammals and sea turtles, as required by the NEG Port's MARAD/USCG License and NOAA Fisheries BO, and as described in section 11, exceed the modeled distances. These requirements successfully supported construction activities and remain applicable and appropriate for any future maintenance and repair activities.

There may also be certain circumstances that require the presence of an EBRV at the NEG Port to support maintenance and repair activities (e.g., maintenance and repair on the STL Buoy, vessel commissioning, and any onboard equipment malfunction or failure occurring while a vessel is present for cargo delivery). As stated previously, the potential noise effects would only be associated with underwater acoustic harassment of marine mammals and sea turtles from the use of thrusters during mooring and unmooring. Mitigation and monitoring strategies are already in place to mitigate for such effects when EBRVs are transiting within the designated TSS, transiting to the Broad Sound Anchorage area, maneuvering within the Port's Area to be Avoided, transiting between Port Buoys, and/or while actively engaging in the use of thrusters. Therefore, acoustic impacts associated with EBRV-supported maintenance and/or repair activities at the Port under the Proposed Action would be the same as those described for Port operations.

#### **1.4.2 Algonquin Pipeline Lateral O&M Activities**

As stated in section 1.3.2.1, routine inspections of the Algonquin Pipeline Lateral are conducted annually by a ROV launched from a vessel of opportunity. Planned O&M activity is the annual inspection of the cathodic protection monitors by a ROV. The monitors are located at the ends of the Algonquin Pipeline Lateral and the adjacent Flowlines. Each inspection activity will take approximately 3 days and will utilize a ROV launched from a vessel of opportunity. The most likely vessel will be similar to the NEG Port's normal support vessel referenced in section 1.3.1.2.

In addition to these routine activities, there may be instances whereby unanticipated events at the NEG Port and Algonquin Pipeline Lateral necessitate emergency maintenance and/or repair activities. While the extent and number of such maintenance and repair activities at the Port over its expected 25 year life cannot be accurately estimated, it is reasonable to assume that a worst-case maintenance and/or repair scenario would result in similar types of activities and require the use of similar support vessels and equipment as used for construction.

Modeling analysis conducted in support of the final EIS/EIR concluded that the only underwater noise of critical concern during NEG Port and Algonquin Pipeline Lateral construction would be from vessel noises such as turning screws, engine noise, noise of operating machinery, and thruster use. As with construction noise at the NEG Port, to confirm modeled results and better understand the noise footprint

associated with construction activities along the Algonquin Pipeline Lateral, field measurements were taken of various construction activities during the 2007 NEG Port and Algonquin Pipeline Lateral Construction period (see Table 1-1). Again, as detailed in section 1.4.1.1., measurements were taken and normalized to establish the “loudest” potential construction measurement event. Two positions within Massachusetts Bay were then used to determine site-specific distances to the 120/160/180 dB isopleths:

- Construction Position 2. PLEM: 70° 46.755' W and 42° 28.764' N
- Construction Position 3. Mid-Pipeline: 70° 40.842' W and 42° 31.328' N

As described for NEG Port operations and maintenance and repair, at each location sound propagation calculations were performed to determine the noise footprint of the construction activity at each of the specified locations. The calculations took into consideration the same aspects and evaluations as described in sections 1.4.1.1 and 1.4.1.2. Results were then summed across frequencies to provide the broadband received levels at receptor locations. Appendix C provides a detailed description of the propagation calculation methodologies employed. Table 1-5 provides a summary of the resultant underwater sound pressure levels and distance to the 120/160 dB isopleths by activity type and identified position. As identified in Table 1-5, none of the modeled activities were found to reach the 160 dB isopleths at any appreciable distance from the sources evaluated. As with NEG Port operations and maintenance and repair, it is important to note that the results presented in Table 1-5, do not include existing acoustic underwater ambient conditions which may effectively mask project sounds at sufficient distances. Elevated underwater sound levels within Massachusetts Bay due to this existing vessel traffic and other Bay activities may effectively mask sound generated during Port and Pipeline activities. Sound levels recorded by MARUs within frequency bands for marine mammals have been reported to include whales, other biotic and abiotic sound sources and ambient noise that could be occurring at the time (BRP 2011).

**Table 1-5 Resultant underwater sound pressure levels and distance to threshold levels during Algonquin Pipeline Lateral Construction**

	Estimated Distance (meters) from source at which Sound Pressure Level falls below 160 dBL	Estimated Distance (meters) from source at which Sound Pressure Level falls below 120 dBL
<b>Pipeline Lateral: Construction</b>		
Barge / Tug (pulling and pushing) / Construction Vessel / Barge Position 2: PLEM	n/a	3500
Barge / Tug (pulling and pushing) / Construction Vessel / Barge Position 3: Mid-pipeline	n/a	2831

The resulting distances to the 120/160 dB isopleths have been conservatively estimated to determine the maximum distance at which Level B harassment may occur. Impulsive pressure levels produced by thrusters during maneuvering of construction vessels drop quickly below the 160 dB isopleth. While the latest modeling data shows an increase in distance out to the 120 dB isopleth, current mitigation and monitoring requirements to avoid and/or minimize harassment of marine mammals and sea turtles, as required by the NEG Port’s MARAD/USCG License and NOAA Fisheries BO, and as described in section 11, exceed the modeled distances. These requirements successfully supported construction

activities and remain applicable and appropriate for any future Algonquin Pipeline Lateral maintenance and repair activities.

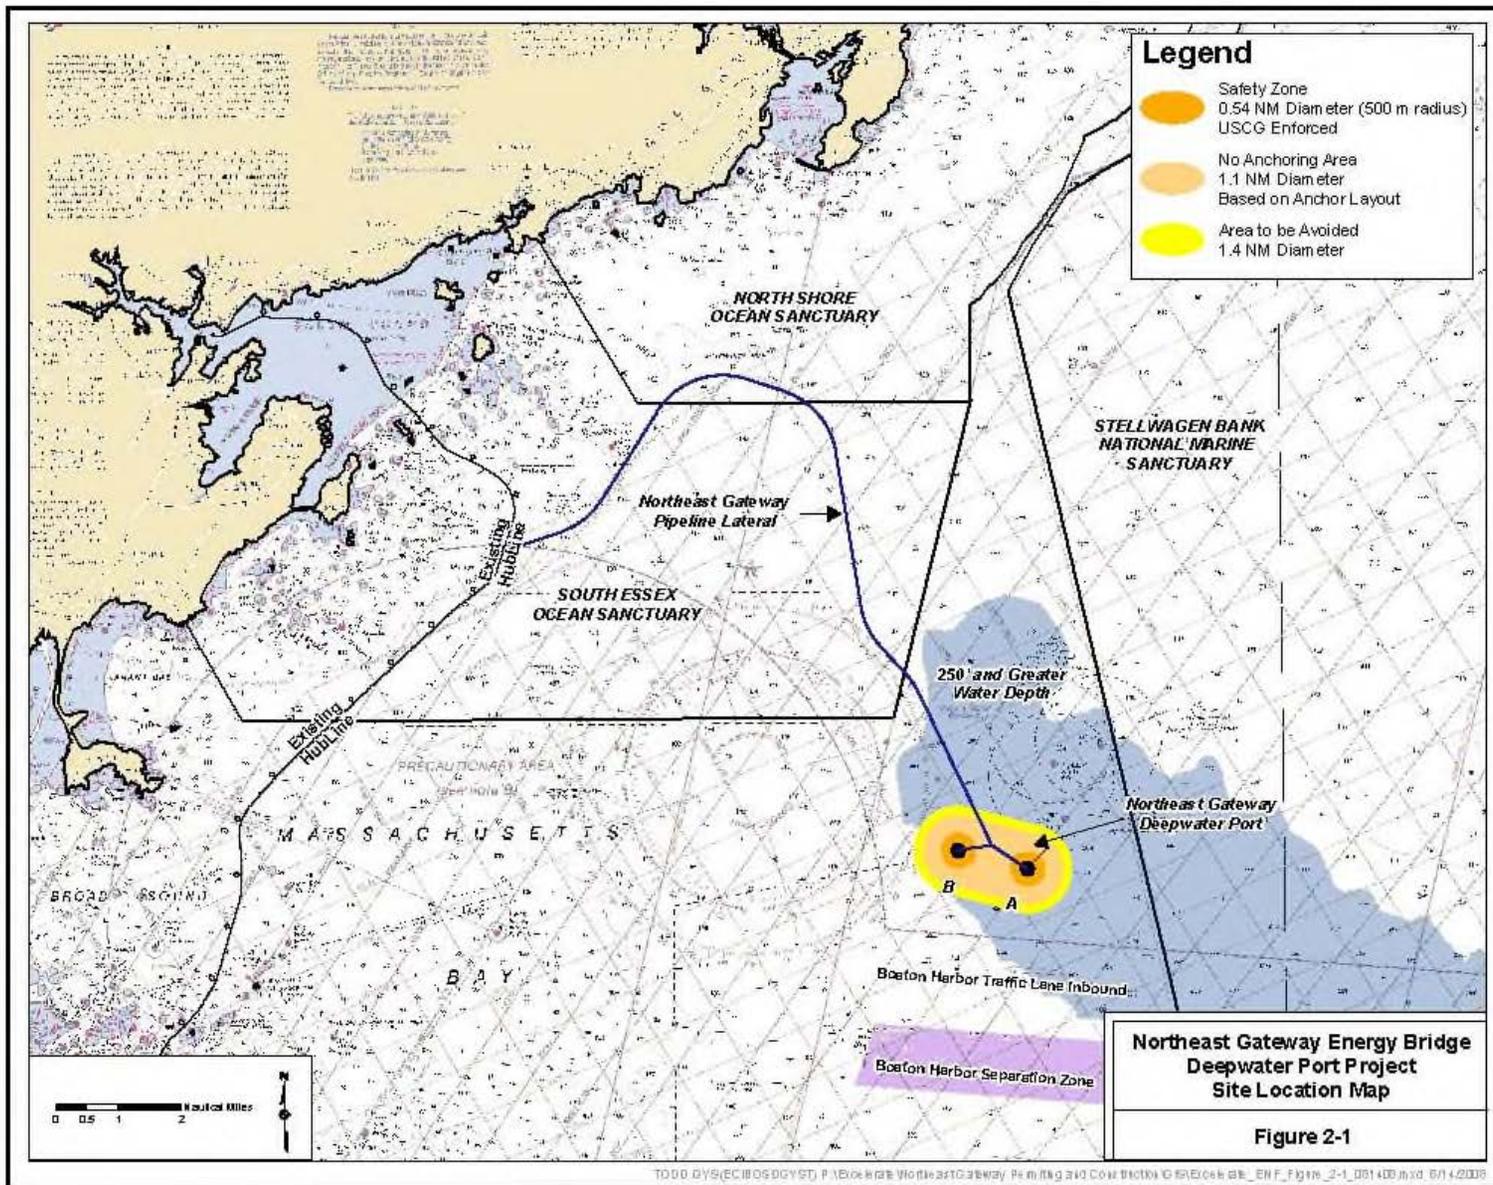

## **2.0 DATES, DURATION AND LOCATION OF NEG PORT AND ALGONQUIN PIPELINE LATERAL OPERATIONS**

### **2.1 Operation Dates and Duration**

The NEG Port completed commissioning activities on February 27, 2008, enabling the facility to receive natural gas and to begin its operations. The NEG Port is expected to receive LNG cargo deliveries for the design life of the facility of about 40 years.

### **2.2 Specific Geographic Region**

The NEG Port is located at 42° 23' 38.46" N/70° 35' 31.02" W for Buoy A and 42° 23' 56.40 N/70° 37' 0.36" W for Buoy B in Massachusetts Bay. The Algonquin Pipeline Lateral begins near milepost (MP) 8 on the existing HubLine pipeline in waters approximately 3 miles (4.8 kilometers) to the east of Marblehead Neck in Marblehead, Massachusetts. From the HubLine connection (MP 0.0), the Algonquin Pipeline Lateral route extends northeast, crossing the outer reaches of the territorial waters of the Town of Marblehead, the City of Salem, the City of Beverly, and the Town of Manchester-by-the-Sea for approximately 6.3 miles (10.1 kilometers). At MP 6.3, the Algonquin Pipeline Lateral route curves to the east and southeast, exiting Manchester-by-the-Sea territorial waters and entering waters regulated by the Commonwealth of Massachusetts. The Algonquin Pipeline Lateral route continues to the south/southeast for approximately 6.2 miles (10 kilometers) to MP 12.5, where it exits state waters and enters federal waters. The Algonquin Pipeline Lateral route then extends to the south for another approximately 3.5 miles (5.7 kilometers), terminating at the NEG Port. The NEG Port and Algonquin Pipeline Lateral are depicted in Figure 2-1.

### 3.0 MARINE MAMMAL SPECIES AND NUMBERS

Marine mammals known to traverse or occasionally visit the waters within the area of the NEG Port and Algonquin Pipeline Lateral include both threatened or endangered species, as well as those species that are not threatened or endangered. Marine mammals both protected under the MMPA as amended in 1994 and those that are listed as threatened or endangered under the Endangered Species Act are discussed in detail in sections 3.2.4 and 3.3 of the USCG final EIS/EIR issued for this project. As shown in Table 3-1, 20 marine mammal species have the possible or confirmed occurrences within the marine waters of Massachusetts Bay.

**Table 3-1 Marine Mammals Known to Occur in the Marine Waters of Massachusetts Bay**

Common Name	Scientific Name	NOAA Fisheries Status	Time of Year in Massachusetts Bay
<b>Toothed Whales (Odontoceti)</b>			
Atlantic white-sided dolphin	<i>Lagenorhynchus acutus</i>	Non-strategic	Year round
Bottlenose dolphin	<i>Tursiops truncatus</i>	Non-strategic	Late summer, early fall
Short-beaked common dolphin	<i>Delphinus delphis</i>	Non-strategic	Fall and winter
Harbor porpoise	<i>Phocoena phocoena</i>	Strategic	Year round (Sept-April peak)
Killer whale	<i>Orcinus orca</i>	Non-strategic	July-Sept
Long-finned pilot whale	<i>Globicephala malaena</i>	Non-strategic	Year round (Sept-April peak)
Risso's dolphin	<i>Grampus griseus</i>	Non-strategic	Spring, summer, autumn
Striped dolphin	<i>Stenella coeruleoalba</i>	Non-strategic	Year round
White-beaked dolphin	<i>Lagenorhynchus albirostris</i>	Non-strategic	April-Nov
Sperm whale	<i>Physeter macrocephalus</i>	Endangered	Pelagic
<b>Baleen Whales (Mysticeti)</b>			
Minke whale	<i>Balaenoptera acutorostrata</i>	Non-strategic	April-Oct
Blue whale	<i>Balaenoptera musculus</i>	Endangered	Aug-Oct
Fin whale	<i>Balaenoptera physalus</i>	Endangered	April-Oct
Humpback whale	<i>Megaptera novaeangliae</i>	Endangered	April-Oct
North Atlantic right whale	<i>Eubalaena glacialis</i>	Endangered	Jan-Jul (year round)
Sei whale	<i>Balaenoptera borealis</i>	Endangered	May-Jun
<b>Earless Seals (Phocidae)</b>			
Gray seals	<i>Halichoerus grypus</i>	Non-strategic	Year round
Harbor seals	<i>Phoca vitulina</i>	Non-strategic	Late Sept-early May
Hooded seals	<i>Cystophora cristata</i>	Non-strategic	Jan-May
Harp seal	<i>Phoca groenlandica</i>	Non-strategic	Jan-May

### 4.0 AFFECTED SPECIES STATUS AND DISTRIBUTION

The status, distribution, and seasonal distribution of affected species or stocks that may be affected by the operation of the NEG Port and Algonquin Pipeline Lateral are discussed in detail in sections 3.2.4 and 3.3 of the USCG final EIS/EIR issued for this NEG Port and Algonquin Pipeline Lateral, and in Table 3-1.

In general, Risso's dolphins, striped dolphins, sperm whales, hooded seals, and harp seals range outside the NEG Port area, usually in more pelagic waters. Additionally, the sei whale, also a more pelagic and northern species, generally ranges outside the NEG Port area. On October 6, 2011, NOAA Fisheries issued an IHA to Northeast Gateway which authorizes the incidental harassment of species more

commonly found in the shelf waters of Massachusetts Bay and that could potentially be encountered in the NEG Port area. These species include the gray seal, harbor seal, harbor porpoise, Atlantic white-sided dolphin, short-beaked common dolphin, bottlenose dolphin, long-finned pilot whale, killer whale, minke whale, North Atlantic right whale, humpback whale, and fin whale. These species, with the exception of the short-beaked common dolphin, bottlenose dolphin and killer whale, are the only ones observed during intensive right whale surveys (2001 to 2005) in nearby Cape Cod by the Provincetown Center for Coastal Studies. The short-beaked common dolphin, bottlenose dolphin and killer whale were also not observed during NEG Port and Algonquin Pipeline Lateral construction activities during the months of May through November 2007 (see Appendix D), or during operational activities in the 2008 and 2009 operational periods (see Appendix E and F). Additionally, the bottlenose dolphin and killer whale were not observed during operational activities during the 2010 through 2011 operational period (see Appendix G and H). However, given their potential for occurrence in the vicinity of the NEG Port and Algonquin Pipeline Lateral area, and the sighting of short-beaked common dolphin during the 2010 operational period (see Appendix G), Northeast Gateway and Algonquin request harassment authorization for all 13 species under this application. A general summary of each of these species is provided in the following sections.

#### **4.1 Toothed Whales (Odontoceti)**

##### **Long-finned pilot whale (*Globicephala melas*) – Non-Strategic**

The long-finned pilot whale is more generally found along the edge of the continental shelf (a depth of 330 to 3,300 feet [100 to 1,000 meters]), choosing areas of high relief or submerged banks in cold or temperate shoreline waters. This species is split between two subspecies: the Northern and Southern subspecies. The Southern subspecies is circumpolar with northern limits of Brazil and South Africa. The Northern subspecies, which could be encountered during operation of the NEG Port, ranges from North Carolina to Greenland (Reeves et al. 2002; Wilson and Ruff 1999). In the western North Atlantic, long-finned pilot whales are pelagic, occurring in especially high densities in winter and spring over the continental slope, then moving inshore and onto the shelf in summer and autumn following squid and mackerel populations (Reeves et al. 2002). They frequently travel into the central and northern Georges Bank, Great South Channel, and Gulf of Maine areas during the summer and early fall (May and October) (NOAA 1993). According to the species stock report, the population estimate for the Gulf of Maine/Bay of Fundy long-finned pilot whale is unknown, however the best estimate of approximately 31,139 individuals should be used as it covers the preferred habitat for this species (Waring et al. 2010).

They feed preferentially on squid but will eat fish (e.g., herring) and invertebrates (e.g., octopus, cuttlefish) if squid are not available. They also ingest shrimp (particularly younger whales) and various other fish species occasionally. These whales probably take most of their prey at depths of 600 to 1,650 feet (200 to 500 meters), although they can forage deeper if necessary (Reeves et al. 2002). As a very social species, long-finned pilot whales travel in pods of roughly 20 individuals while following prey. These small pods are thought to be formed around adult females and their offspring. Behaviors of long-finned pilot whales range from quiet rafting or milling on the surface, to purposeful diving, to bouts of playfulness.

The long-finned pilot whales are subject to bycatch during gillnet fishing, pelagic trawling, longline fishing, and purse seine fishing. Approximately 215 pilot whales were killed or seriously injured each year by human activities during 1997 to 2001. Strandings involving hundreds of individuals are not unusual and demonstrate that these large schools have a high degree of social cohesion (Reeves et al. 2002). The species is not listed as “strategic” by NOAA Fisheries because the 2003-2007 estimated

average annual human-related mortality does not exceed the potential biological removal for this species. However, issues with an inability to distinguish between species of long-finned and short-finned pilot whales, and the fact that abundance estimates and associated potential biological removal are not available, it is possible that mortality for both stocks of this species could exceed the potential biological removal (Waring et al. 2010).

**Harbor porpoise (*Phocoena phocoena*) – Strategic**

The harbor porpoise inhabits shallow, coastal waters, often found in bays, estuaries, and harbors. In the western Atlantic, they are found from Cape Hatteras north to Greenland. They are common visitors to Massachusetts Bay during September through April. During the spring, they are found from the Bay of Fundy to south of Cape Cod. They concentrate in southwestern Gulf of Maine, Great South Channel, Jeffreys Ledge, and coastal Maine during the mid-spring months. After April, they migrate north towards the Gulf of Maine and Bay of Fundy. They generally eat small schooling fish such as mackerel, herring, and cod, as well as worms, squid, and sand eel (ACSONline 2004; NOAA 1993). According to the species stock report, the population estimate for the Gulf of Maine/Bay of Fundy harbor porpoise is 89,700 individuals (Waring et al. 2004).

The most common threat to the harbor porpoise is from incidental mortality from fishing activities, especially from bottom-set gillnets. It has been demonstrated that the porpoise echolocation system is capable of detecting net fibers, but they must not have the “system activated” or else they fail to recognize the nets (Reeves et al. 2002). Roughly 365 harbor porpoises are killed by human-related activities each year. In 1999, a Take Reduction Plan to reduce harbor porpoise bycatch in U.S. Atlantic gillnets was implemented. The plan that pertains to the Gulf of Maine focuses on sink gillnets and other gillnets that can catch groundfish in New England waters. The ruling implements time and area closures, some of which are complete closures, as well as requiring pingers on multispecies gillnets. In 2001, the harbor porpoise was removed from the candidate species list for the Endangered Species Act of 1973; a review of the biological status of the stock indicated that a classification of “Threatened” was not warranted (Waring et al. 2009). However, this species has been listed as “strategic” because average annual human-related mortality and injury exceeds the potential biological removal (Waring et al. 2010).

**Atlantic white-sided dolphin (*Lagenorhynchus acutus*) – Non-Strategic**

The Atlantic white-sided dolphin is typically found at a depth of 330 feet (100 meters) in the cool temperate and subpolar waters of the North Atlantic, generally along the continental shelf between the Gulf Stream and the Labrador current to as far south as North Carolina (Bulloch 1993; Reeves et al. 2002).

NOAA Fisheries recognizes the potential for three stocks of the Atlantic white-sided dolphin in the western North Atlantic: a Gulf of Maine stock, a Gulf of St. Lawrence stock, and a Labrador Sea stock (Waring et al. 2009). The Gulf of Maine stock occupies regions of both the Gulf of Maine (usually in the southwestern portion) and Georges Bank throughout the entire year. High-use areas for this species are widely located either side of the 328-foot (100 meters) isobath along the northern edge of Georges Bank, and north from the Great South Channel to Stellwagen Bank, Jeffreys Ledge, Platts Bank, and Cashes Ledge. In spring, high-use areas existed in the Great South Channel, northern Georges Bank, the steeply sloping edge of Davis Bank and Cape Cod, southern Stellwagen Bank, and the waters between Jeffreys Ledge and Platts Bank. In summer, high-use areas tend to shift and expand toward the east and northeast along most of the northern edge of Georges Bank between the 164- and 656-foot (50- and 200-meter) isobaths and northward from the Great South Channel along the slopes of Davis Bank and Cape Cod. In winter, high sightings occur at the northern tip of Stellwagen Bank and Tillies Basin (NOAA 2008).

This species is highly social and is commonly seen feeding with fin whales. They feed on a variety of fish such as herring, hake, smelt, capelin, and cod, as well as squid (NOAA 1993). Estimates of population size, estimated through an average of surveys conducted in August between 2002 and 2006, indicate that the population of the North Atlantic stock is approximately 63,368 individuals (Waring et al. 2010).

The biggest human-induced threat to the Atlantic white-sided dolphin is bycatch, because they are occasionally caught in fishing gillnets and trawling equipment. An estimated average of 328 dolphins each year were killed by fishery-related activities during 2003 to 2007 (Waring et al. 2010). Average annual fishery-related mortality and serious injury does not exceed the potential biological removal for this species; therefore, NOAA Fisheries considers this species as “non-strategic” (Waring et al. 2010).

**Killer whale (*Orcinus orca*) – Non-Strategic**

The black-and-white killer whale is the largest member of the dolphin family, roughly 22 to 30 feet (6.7 to 9.1 meters) long and nearly 9,000 pounds (4,080 kilograms). This species is found in all of the world’s oceans with highest densities in the high latitudes (Wilson and Ruff 1999). Killer whales do not maintain a regular migration route because they generally migrate towards viable food sources, which are likely to be schools of bluefin tuna. Killer whale presence in the waters off the east coast of the United States is considered uncommon (Katona et al. 1988; Waring et al. 2004). When encountered, they are seen in the southwestern Gulf of Maine from mid-July to September. Killer whales have been found to overwinter in the Gulf of Maine and were seen on Jeffreys Ledge between the Isles of Shoals and Stellwagen Bank (NOAA 1993). They feed on a variety of fish, including tuna, herring, and mackerel, and have also been known to attack seals, seabirds, and other cetaceans such as large baleen and sperm whales (NOAA 1993; Blaylock et al. 1995). According to the species stock report, the population estimate for the western North Atlantic stock of killer whales is unknown (Blaylock et al. 1995).

The killer whale is not endangered, although whaling or live-capture operations have depleted some regional populations. They are threatened by pollution, heavy ship traffic, and possibly reduced prey abundance. There have been no observed mortalities or serious injuries by NOAA Fisheries Sea Samplers in the pelagic drift gillnet, pelagic longline, pelagic pair trawl, New England multispecies sink gillnet, mid-Atlantic coastal sink gillnet, or the North Atlantic bottom trawl fisheries (Blaylock et al. 1995). Recent evidence has also indicated that they are subject to biomagnification of toxic substances (ACSONline 2004). Average annual fishery-related mortality and serious injury does not exceed the potential biological removal for this species; therefore, NOAA Fisheries considers this species as “non-strategic” (Blaylock et al. 1995).

Although this species is one of the most widely distributed small cetacean species in the world, they are not commonly seen in the vicinity of the NEG Port and Algonquin Pipeline Lateral in Massachusetts Bay (NOAA 2008). No confirmed sightings of this species have occurred during construction and/or operation of the NEG Port and Algonquin Pipeline Lateral (Northeast Gateway 2007; Northeast Gateway 2008; Northeast Gateway 2009; Northeast Gateway 2010; Northeast Gateway 2011).

**Short-beaked common dolphin (*Delphinus delphis*) – Non-Strategic**

Short-beaked common dolphins can be found either along the 200- to 2,000-meter (650- to 6,500-foot) isobaths over the continental shelf and in pelagic waters of the Atlantic and Pacific Oceans. They are present in the western Atlantic from Newfoundland to Florida. The short-beaked common dolphin is especially common along shelf edges and in areas with sharp bottom relief such as seamounts and escarpments (Reeves et al. 2002). They show a strong affinity for areas with warm, saline surface waters. Off the coast of the eastern United States, they are particularly abundant in continental slope waters from

Georges Bank southward to about 35 degrees north (Reeves et al. 2002) and usually inhabit tropical, subtropical, and warm-temperate waters (Waring et al. 2009).

The long-beaked dolphin is more common in coastal waters, where the short-beaked dolphin inhabits offshore waters. If they do come to the Massachusetts Bay area to feed, it is usually during the fall and winter (NOAA 1993). According to the species stock report, the best population estimate for the western North Atlantic common dolphin is approximately 120,743 individuals (Waring et al. 2009).

These dolphins typically gather in schools of hundreds of thousands, although the schools generally consist of smaller groups of 30 or fewer. They are eager bow riders and are active at the surface (Reeves et al. 2002). The short-beaked common dolphin feeds on small schooling fish and squid. They have been known to feed on fish escaping from fishermen's nets or fish that are discarded from boats (NOAA 1993).

The short-beaked common dolphin is also subject to bycatch. It has been caught in gillnets, pelagic trawls, and during longline fishery activities. During 2003 to 2007, an estimated average of approximately 160 dolphins were killed each year by human activities. Average annual fishery-related mortality and serious injury does not exceed the potential biological removal for this species; therefore, NOAA Fisheries considers this species as "non-strategic" (Waring et al. 2009).

Although this species is one of the most widely distributed small cetacean species in the world, they are not commonly seen in the vicinity of the NEG Port and Algonquin Pipeline Lateral in Massachusetts Bay (NOAA 2008). No confirmed sightings of this species have occurred during construction and/or operation of the NEG Port and Algonquin Pipeline Lateral during the operating periods between 2008 and 2011 operating periods. (Northeast Gateway 2007; Northeast Gateway 2008; Northeast Gateway 2009; Northeast Gateway 2010; Northeast Gateway 2011).

#### **Bottlenose dolphin (*Tursiops truncatus*) – Non-Strategic**

The bottlenose dolphin is a light- to slate-gray dolphin, roughly 8 to 12 feet (2.4 to 3.7 meters) long with a short, stubby beak. Because this species occupies a wide variety of habitats, it is regarded as possibly the most adaptable cetacean (Reeves et al. 2002). It occurs in oceans and peripheral seas at both tropical and temperate latitudes. In North America, bottlenose dolphins are found in surface waters with temperatures ranging from 50 to 90 °F (10 to 32 °C).

There are two distinct bottlenose dolphin populations: shallow water and deepwater population. The shallow water, coastal population resides along the inner continental shelf and around islands. These animals often move into or reside in bays, estuaries, and the lower reaches of rivers (Reeves et al. 2002). The deepwater population is the only one found in the northern latitudes of the North Atlantic, typically in Gulf Stream waters. This deepwater population extends along the entire continental shelf-break from Georges Bank to Cape Hatteras during the spring and summer months, and has been observed in the Gulf of Maine during the late summer and fall. The NOAA Fisheries species stock assessment report estimates the population of western North Atlantic offshore bottlenose dolphin stock at approximately 81,588 individuals (Waring et al. 2009).

Bottlenose dolphins feed on a large variety of organisms, depending on their habitat. The coastal, shallow population tends to feed on benthic fish and invertebrates, while deepwater populations consume pelagic or mesopelagic fish such as croakers, sea trout, mackerel, mullet, and squid (Reeves et al. 2002). Bottlenose dolphins appear to be active both during the day and night. Their activities are influenced by the seasons, time of day, tidal state, and physiological factors such as reproductive seasonality (Wells and Scott 2002).

The biggest threat to the population is bycatch because they are frequently caught in fishing gear, gillnets, purse seines, and shrimp trawls (Waring et al. 2009). They have also been adversely impacted by pollution, habitat alteration, boat collisions, human disturbance, and are subject to bioaccumulation of toxins. Scientists have found a strong correlation between dolphins with elevated levels of PCBs and illness, indicating certain pollutants may weaken their immune system (ACSONline 2004). NOAA Fisheries considers this species as “non-strategic”; however, average annual fishery-related mortality and serious injury between 2002 and 2006 has not been estimated, and it is therefore unknown whether or not total mortality and serious injury can be considered insignificant. (Waring et al. 2009).

Although this species is one of the most widely distributed small cetacean species in the world, they are not commonly seen in the vicinity of the NEG Port and Algonquin Pipeline Lateral in Massachusetts Bay (NOAA 2008). No confirmed sightings of this species have occurred during construction and/or operation of the NEG Port and Algonquin Pipeline Lateral (Northeast Gateway 2007; Northeast Gateway 2008; Northeast Gateway 2009; Northeast Gateway 2010; Northeast Gateway 2011).

#### **Risso’s dolphin (*Grampus griseus*) – Non-Strategic**

Risso’s dolphins are commonly found in the deeper waters of the U.S. east coast continental shelf edge and oceanic waters ranging from Cape Hatteras to Georges Bank, mainly during spring, summer and autumn (CETAP 1982; Payne et al. 1984). There is currently no information on stock structure of this species for western North Atlantic; therefore, it is not possible to determine if separate stocks exist in the Gulf of Mexico and Atlantic (Waring et al. 2010). The best estimate of abundance for the western North Atlantic stock of Risso’s dolphins is 20,479 animals (Waring et al., 2010). There are insufficient data to determine the population trend for this stock.

The biggest threat to the population is bycatch because they have been caught in fishing gear such as drift gillnets, pelagic longline, pair trawls and mid-water trawls (Waring et al. 2010). NOAA Fisheries considers this species as “non-strategic”; however, average annual fishery-related mortality and serious injury between 2004 and 2008 was not less than 10 percent of the potential biological and cannot be considered insignificant. (Waring et al. 2010).

Although this species is one of the most widely distributed small cetacean species in the world, they are not commonly seen in the vicinity of the NEG Port and Algonquin Pipeline Lateral in Massachusetts Bay (NOAA 2008). No confirmed sightings of this species have occurred during construction and/or operation of the NEG Port and Algonquin Pipeline Lateral (Northeast Gateway 2007; Northeast Gateway 2008; Northeast Gateway 2009; Northeast Gateway 2010; Northeast Gateway 2011).

## **4.2 Baleen Whales (Mysticeti)**

#### **North Atlantic right whale (*Eubalaena glacialis*) – Endangered**

The North Atlantic right whale is a baleen whale and one of the most endangered large whale species in the world. The North Atlantic right whale has seen little to no recovery since it was listed as a protected species. This is a drastic difference from the stock found in the Southern Hemisphere, which has increased at a rate of 7 to 8 percent (Knowlton and Kraus 2001).

From the 2003 United States Atlantic and Gulf of Mexico Marine Mammal Stock Assessments, there were only 291 North Atlantic right whales in existence, which is less than what was reported in the Northern Right Whale Recovery Plan written in 1991 (NOAA Fisheries 1991a; Waring et al. 2004). This is a tremendous difference from pre-exploitation numbers, which are thought to be around 1,000 individuals. When the right whale was finally protected in the 1930s, it is believed that the North Atlantic

right whale population was roughly 100 individuals (Waring et al. 2004). In 2005, the Western North Atlantic population size was estimated to be at least 345 individuals (Waring et al. 2010)

There are six major habitats or congregation areas for western North Atlantic right whales: coastal waters of the southeastern United States, Great South Channel, Georges Bank/Gulf of Maine, Cape Cod and Massachusetts Bays, Bay of Fundy, and the Scotian Shelf (Waring et al. 2010). New England waters are a primary feeding habitat for the North Atlantic right whale. North Atlantic right whales inhabit the waters off New England throughout the year, but their presence is highest in the Massachusetts Bay area during the winter/spring months. In the spring, the highest abundance of right whales is located over the deeper waters (328- to 525-foot [100- to 160-meter] isobaths) on the northern edge of the Great South Channel and deep waters (328 to 984 feet, 100 to 300 meters) parallel to the 328-foot (100-meter) isobath of northern Georges Bank and Georges Basin. High abundance was also found in the shallowest waters (<98 feet [< 30 meters]) of Cape Cod Bay, over Platts Bank and around Cashes Ledge. In the summer months, right whales move almost entirely away from the coast to deep waters over basins in the central Gulf of Maine (Wilkinson Basin, Cashes Basin between the 525- and 656-foot [160- and 200-meter] isobaths) and north of Georges Bank (Rogers, Crowell, and Georges Basins). Highest abundance was found north of the 328-foot (100-meter) isobath at the Great South Channel and over the deep slope waters and basins along the northern edge of Georges Bank. The waters between Fippennies Ledge and Cashes Ledge are also estimated as high-use areas. In the fall months, right whales have been sighted infrequently in the Gulf of Maine, with highest densities over Jeffreys Ledge and over deeper waters near Cashes Ledge and Wilkinson Basin. In winter, Cape Cod Bay, Scantum Basin, Jeffreys Ledge, and Cashes Ledge are the main high-use areas (NOAA 2008).

The primary prey for North Atlantic right whales off the coast of Massachusetts are zooplankton (i.e., copepods) (Kelly 1995). Right whales are considered grazers as they swim slowly with their mouths open. They are the slowest swimming whales and can only reach speeds up to 10 miles (16 kilometers) per hour. They can dive at least 1,000 feet (300 meters) and stay submerged for typically 10 to 15 minutes, feeding on their prey below the surface (ACSONline 2004).

Most ship strikes are fatal to the North Atlantic right whales (Jensen and Silber 2004). Right whales have difficulty maneuvering around boats. North Atlantic right whales spend most of their time at the surface, feeding, resting, mating, and nursing, increasing their vulnerability to collisions. Mariners should assume that North Atlantic right whales will not move out of their way nor will they be easy to detect from the bow of a ship for they are dark in color and maintain a low profile while swimming (WWF 2005).

### **Humpback whale (*Megaptera novaeangliae*) – Endangered**

Humpback whales were commercially exploited by whalers throughout their whole range until they were protected in the North Atlantic in 1955 by the International Whaling Commission (IWC) ban. Before whaling activities, it was thought that the abundance of whales in the North Atlantic stock was in excess of 15,000 (Nowak 2002). Today, less than 10 percent of the initial population exists (NOAA Fisheries 1991b). According to the species stock assessment report, the best estimate of abundance for the Gulf of Maine stock of humpback whales is 847 individuals (Waring et al. 2010).

The humpback whale is found in all of the world's oceans and it follows a normal migration route of feeding in the temperate and polar waters in the summer and mating and calving in tropical waters during the winter. Humpback whales inhabit waters mainly over the continental shelves; they stay along the edges and around some of the oceanic islands (NOAA Fisheries 1991b; NOAA 1993). There are 13 separate stocks of humpback whales worldwide (NOAA Fisheries 1991b). Through genetic analysis of

the whales inhabiting the Gulf of Maine, it was determined that the Gulf of Maine has its own feeding stock. Most individuals arrive in early March to Massachusetts Bay from wintering grounds in eastern central Caribbean. The highest abundance for humpback whales is distributed primarily along a relatively narrow corridor following the 328-foot (100-meter) isobath across the southern Gulf of Maine from the northwestern slope of Georges Bank, south to the Great South Channel, and northward alongside Cape Cod to Stellwagen Bank and Jeffreys Ledge. The relative abundance of whales increases in the spring with the highest occurrence along the slope waters (between the 131- and 459-foot [40- and 140-meter] isobaths) off Cape Cod and Davis Bank, Stellwagen Basin, and Tillies Basin and between the 164- and 656-foot (50- and 200-meter) isobaths along the inner slope of Georges Bank. High abundance is also estimated for the waters around Platts Bank. In the summer months, abundance increases over the shallow waters (<164 feet, or <50 meter) of Stellwagen Bank, the waters (328 to 656 feet [100 to 200 meters]) between Platts Bank and Jeffreys Ledge, the steep slopes (between the 98- and 525-foot [30- and 160-meter] isobaths) of Phelps and Davis Bank north of the Great South Channel towards Cape Cod, and between the 164- and 328-foot (50- and 100-meter) isobath for almost the entire length of the steeply sloping northern edge of Georges Bank. This general distribution pattern has persisted in all seasons except winter, when humpbacks remained at high abundance in only a few locations, including Porpoise and Neddick Basins adjacent to Jeffreys Ledge, northern Stellwagen Bank and Tillies Basin, and the Great South Channel (NOAA 2008).

Humpback whales are thought to feed mainly while migrating and in summer feeding areas; little feeding is known to occur in their wintering grounds. Humpbacks feed over the continental shelf in the North Atlantic between New Jersey and Greenland, consuming roughly 95 percent small schooling fish and 5 percent zooplankton (i.e., krill), and they will migrate throughout their summer habitat to locate prey (Kenney and Winn 1986). They swim below the thermocline to pursue their prey, so even though the surface temperatures might be warm, they are frequently swimming in cold water (NOAA Fisheries 1991b).

Stellwagen Bank has been identified as an important nursery for humpback mothers with calves. Herring, sand lance, and capelin are the primary prey species for the Gulf of Maine stock but they also eat haddock, mackerel, small pollock, cod, and hake (NOAA Fisheries 1991b). Data found in the Northeast Gateway Environmental Impact Statement Baseline Evaluation show an increase in humpback whale sightings near the project area in 2002, with declining numbers seen since. There is no significant change in sightings between the periods 1995 to 1999 and 2000 to 2004 (Weinrich and Sardi 2005).

The biggest threats to humpback whales are gear entanglements and ship strikes. Approximately three humpback whales were killed each year by anthropogenic factors such as ship strikes and fishery-related incidents during 1997 to 2001. During one study of humpback whale carcasses, anthropogenic factors either contributed to or caused the death of 60 percent of the stranded whales (Wiley et al. 1995 as reported in Waring et al. 2010). Another study found that humpbacks are also subject to bioaccumulation of toxins (Taruski et al. 1975 as reported in NOAA Fisheries 1991b). Increase in ambient noise levels has also had an impact on their utilization of habitats; humpback whales have demonstrated a short-term avoidance of areas with increased whale-watching activity (Corkeron 1995).

The species is listed as Endangered due to the depletion of its population from whaling (NOAA Fisheries 1991b). A recovery plan has been written and is currently in effect (NOAA Fisheries 1991b).

**Fin whale (*Balaenoptera physalus*) – Endangered**

The fin whale is found in all oceans of the world. Fin whales spend the winter in subtropical or offshore waters mating and calving and migrate into cooler temperate to polar waters for feeding during the spring, summer, and fall (Reeves et al. 1998). There has been some controversy regarding the number of fin whale stocks along the eastern coast of the United States. The IWC recognizes one western North Atlantic stock, consisting of whales, which inhabit the waters off New England, north to Nova Scotia, and the southeastern coast of Newfoundland (Donovan 1991 as reported in Waring et al. 2004); however, Breiwick (1993 as reported in Reeves et al. 1998) identified two stocks, one that remains off of Nova Scotia and New England and another that remains in Newfoundland waters. Fin whales are the most common large baleen whale species in the Gulf of Maine/Massachusetts Bay area. They have the largest standing stock and largest food requirements, thus having the largest impact on the ecosystem of any cetacean species (Hain et al. 1992 as reported in Waring et al. 2010). Fin whales are also the most observed cetacean species during whale-watching activities in the northeastern United States.

The waters off New England are an important feeding ground for the fin whale. They generally stay in deeper waters near the edge of the continental shelf (300 to 600 feet; 90 to 180 meters), but will migrate towards coastal areas if prey is available (NOAA 1993). They are known to herd prey such as sea lance, capelin, krill, herring, copepods, and squid for easier consumption (NOAA 1993; EPA 1993). Apparently, the favorite food of fin whales on Stellwagen Bank and in Massachusetts Bay has been sand lance (EPA 1993). According to the species stock assessment report, the best population estimate for the western North Atlantic stock of fin whales, as surveyed in 2006, is 2,269 (Waring et al. 2010). Even though some whales overwinter near Cape Cod, their abundance near Stellwagen Bank peaks between April and October. Off the eastern United States, they are generally found along the 100-meter (330-foot) isobaths, but will follow prey abundance and inhabit shallower water (Reeves et al. 1998).

Spatial patterns of habitat utilization by fin whales are very similar to those of humpback whales. NOAA indicates that spring and summer high-use areas follow the 328-foot (100-meter) isobath along the northern edge of Georges Bank (between the 164- and 656-foot, or 50- and 200-meter, isobaths), and northward from the Great South Channel (between the 164- and 525-foot [50- and 160-meter] isobaths). Waters around Cashes Ledge, Platts Bank, and Jeffreys Ledge are all high-use areas in the summer months. Stellwagen Bank is a high-use area for fin whales in all seasons, with highest abundance occurring over the southern Stellwagen Bank in the summer months. In addition to Stellwagen Bank, high abundance in winter was estimated for Jeffreys Ledge and the adjacent Porpoise Basin 328- to 656-foot (100- to 160-meter) isobaths, as well as Georges Basin and northern Georges Bank (NOAA 2008).

The biggest threats to fin whales are entanglements in gillnets and ship strikes. From 2003 to 2007, the minimum annual rate of mortality for the North Atlantic stock from anthropogenic causes was approximately 2.8 per year (Waring et al. 2010). Increase in ambient noise has also impacted fin whales, for whales in the Mediterranean have demonstrated at least two different avoidance strategies after being disturbed by tracking vessels (Jahoda et al. 2003). Fin whales are the most observed cetacean species during whale-watching activities in the northeastern United States. The species is listed as Endangered due to the depletion of its population from whaling (Reeves et al. 1998). A recovery plan has been written and is available from the NOAA Fisheries for review (Waring et al. 2010).

**Minke whale (*Balaenoptera acutorostrata*) – Non-Strategic**

Minke whales are the smallest and are among the most widely distributed of all the baleen whales. They occur in the North Atlantic and North Pacific, from tropical to polar waters. Currently, scientists recognize two subspecies of the so-called “common” minke whale: the North Atlantic minke and the

North Pacific minke. Generally, they inhabit warmer waters during winter and travel north to colder regions in summer, with some animals migrating as far as the ice edge. They are frequently observed in coastal or shelf waters and in the Massachusetts area, have been recorded in the shallow waters of Stellwagen Bank and southern Jeffreys Ledge from April until October. NOAA indicates that the highest abundance for minke whale is strongly associated with regions between the 164- and 328-foot (50- and 100-meter) isobaths, but with a slightly stronger preference for the shallower waters along the slopes of Davis Bank, Phelps Bank, Great South Channel and Georges Shoals on Georges Bank. Minke whales can be sighted in the Stellwagen Bank National Marine Sanctuary (SBNMS) in all seasons, with highest abundance estimated for the shallow waters (approximately 131 feet [40 meters]) over southern Stellwagen Bank in the summer and fall months. Platts Bank, Cashes Ledge, Jeffreys Ledge, and the adjacent basins (Neddick, Porpoise and Scantium) also supported high relative abundance. Very low densities of minke whales remain throughout most of the southern Gulf of Maine in winter (NOAA 1993; Weinrich and Sardi 2005; Wilson and Ruff 1999). According to the species stock report, the best population estimate for the Canadian east coast stock of minke whales is 3,312 individuals (Waring et al. 2010).

As is typical of the baleen whales, minke whales are usually seen either alone or in small groups, although large aggregations sometimes occur in feeding areas (Reeves et al. 2002). Minke populations are often segregated by sex, age, or reproductive condition. Known for their curiosity, minke whales often approach boats. They feed on schooling fish (i.e., herring, sand eel, capelin, cod, pollock, and mackerel), invertebrates (squid and copepods), and euphausiids. Minke whales basically feed below the surface of the water, and calves are usually not seen in adult feeding areas.

Minke whales are impacted by ship strikes and bycatch from bottom trawls, lobster trap/pot, gillnet and purse seine fisheries. From 2003 to 2007, the minimum annual rate of mortality for the North Atlantic stock from anthropogenic causes was approximately 2.4 per year (Waring et al. 2010). In addition, hunting for Minke whales continues today, by Norway in the northeastern North Atlantic and by Japan in the North Pacific and Antarctic (Reeves et al. 2002). International trade in the species is currently banned. Average annual fishery-related mortality and serious injury does not exceed the potential biological removal for this species; therefore, NOAA Fisheries considers this species as “non-strategic” (Waring et al. 2010).

### **4.3 Earless Seals (Phocidae)**

#### **Harbor seal (*Phocac vitulina*) – Non-Strategic**

Harbor seals are the most abundant seals in eastern United States waters and are commonly found in all nearshore waters of the Atlantic Ocean and adjoining seas above northern Florida; however, their “normal” range is probably only south to New Jersey. In the western North Atlantic, they inhabit the waters from the eastern Canadian Arctic and Greenland, south to southern New England and New York, and occasionally as far south as South Carolina. Some seals spend all year in eastern Canada and Maine, while others migrate to southern New England in late September and stay until late May (Marine Mammal Center 2002; NOAA 1993; Waring et al. 2010). According to the species stock report, the best population estimate for the western North Atlantic stock of harbor seals is 99,340 (Waring et al. 2010).

Harbor seals forage in a variety of marine habitats, including deep fjords, coastal lagoons and estuaries, and high-energy, rocky coastal areas. They may also forage at the mouths of freshwater rivers and streams, occasionally traveling several hundred miles upstream (Reeves et al. 2002). They haul out on

sandy and pebble beaches, intertidal rocks and ledges, and sandbars, and occasionally on ice floes in bays near calving glaciers.

Except for the strong bond between mothers and pups, harbor seals are generally intolerant of close contact with other seals. Nonetheless, they are gregarious, especially during the molting season, which occurs between spring and autumn, depending on geographic location. They may haul out to molt at a tide bar, sandy or cobble beach, or exposed intertidal reef. During this haulout period, they spend most of their time sleeping, scratching, yawning, and scanning for potential predators such as humans, foxes, coyotes, bears, and raptors (Reeves et al. 2002). In late autumn and winter, harbor seals may be at sea continuously for several weeks or more, presumably feeding to recover body mass lost during the reproductive and molting seasons and to fatten up for the next breeding season (Reeves et al. 2002).

Harbor seals are opportunistic feeders feeding on squid and small schooling fish (i.e., herring, alewife, flounder, redfish, cod, yellowtail flounder, sand eel, and hake). They spend about 85 percent of the day diving, and much of the diving is presumed to be active foraging in the water column or on the seabed. They dive to depths of about 30 to 500 feet (10 to 150 meters), depending on location.

Historically, these seals have been hunted for several hundred to several thousand years. Harbor seals are still killed legally in Canada, Norway, and the United Kingdom to protect fish farms or local fisheries (Reeves et al. 2002). From 2003 to 2007, the average rate of mortality for the Western North Atlantic harbor seal stock from anthropogenic causes was approximately 467 per year (Waring et al. 2010). Average annual fishery-related mortality and serious injury does not exceed the potential biological removal for this species; therefore, NOAA Fisheries considers this species as “non-strategic” (Waring et al. 2010).

**Gray seal (*Halichoerus grypus*) – Non-Strategic**

Gray seals inhabit both sides of the North Atlantic in both the temperate and subarctic waters (Morris 2004). Scientists recognize three primary populations of this species, all in the northern Atlantic Ocean. The gray seals that reside in Nantucket Sound are part of the eastern Canada stock, which can be found from northernmost Cape Chidley in Labrador to most recently Long Island Sound (Katona et al. 1993). Gray seals form colonies on rocky island or mainland beaches, though some seals give birth in sea caves or on sea ice, especially in the Baltic Sea. Gray seals prefer haulout and breeding sites that are surrounded by rough seas and riptides where boating is hazardous. Pupping colonies have been identified at Muskegat Island (Nantucket Sound), Monomoy National Wildlife Refuge, and in eastern Maine (Rough 1995). According to the species stock report, the population estimate for the western North Atlantic stock of gray seals is not available; however estimates have been made for certain population segments from different times. In May 2001, the Maine Coast was estimated at 1,731. For the Gulf of St Lawrence and Nova Scotia Eastern Shore during January 2004, the estimate was 52,500. Also in January of 2004, Sable Island population estimates ranged from 208,721 to 223,220 (Waring et al. 2010).

Gray seals are gregarious, gathering to breed, molt, and rest in groups of several hundred or more at island coasts and beaches or on land-fast ice and pack-ice floes. They are thought to be solitary when feeding and telemetry data indicates that some seals may forage seasonally in waters close to colonies, while others may migrate long distances from their breeding areas to feed in pelagic waters between the breeding and molting seasons (Reeves et al. 2002). Gray seals molt in late spring or early summer and may spend several weeks ashore during this time. When feeding, most seals remain within 45 miles (72 kilometers) of their haulout sites. They generally feed on fish (i.e., skates, alewife, sand eel, and herring) and invertebrates.

The biggest threats to gray seals are entanglements in gillnets or plastic debris (Waring et al. 2004). The total estimated human caused mortality from 2003 to 2007 to gray seals was approximately 1,160 per year (Waring et al. 2010). Average annual fishery-related mortality and serious injury does not exceed the potential biological removal for this species; therefore, NOAA Fisheries considers this species as “non-strategic” (Waring et al. 2010).

## **5.0 TYPE OF INCIDENTAL TAKE REQUESTED**

Northeast Gateway and Algonquin request the taking of small numbers of marine mammals pursuant to section 101(a)(5) of the MMPA to authorize the potential non-lethal incidental takes by Level B harassment as defined in the MMPA of small numbers of marine mammals during the O&M of the NEG Port and Algonquin Pipeline Lateral. The request is based upon projected O&M activities for a period of 1 year commencing on October 5, 2012.

Northeast Gateway and Algonquin, in cooperation with the NOAA, the NOAA Fisheries, and the Stellwagen Bank National Marine Sanctuary (SBNMS), have developed comprehensive acoustic and visual monitoring and mitigation measures to minimize potential takes of marine mammals (see sections 11.0 and 13.0 and Appendix A). Given these measures, no take by serious injury or death is likely as a result of NEG Port and Algonquin Pipeline Lateral O&M activities.

### **5.1 NEG Port**

#### **5.1.1 NEG Port Operations**

As detailed in section 1.4.1.1, the only NEG Port operational activities that would generate underwater noise with sounds exceeding the 120 dB threshold for Level B harassment are those stemming from the maneuvering of EBRVs during final docking and/or decoupling maneuvers. No other forms of take are likely or anticipated. The requested take authorization would apply to NEG Port operational activities described regardless of the individual actor (e.g., vessel owner, operator, contractor, etc.) provided that the conditions of the take authorization are met.

On October 6, 2011, NOAA Fisheries issued an IHA to Northeast Gateway Energy Bridge Deepwater Port to take by harassment small numbers of marine mammals incidental to operating a deepwater LNG facility in the Massachusetts Bay. Listed in the issued IHA, under condition 3 – Species Impacted and Level of Takes, are the following 14 species approved for take by Level B Harassment:

North Atlantic right whale (*Eubalaena glacialis*)  
Humpback whale (*Megaptera novaeangliae*)  
Fin whale (*Balaenoptera physalus*)  
Sei whale (*Balaenoptera borealis*)  
Minke whale (*B. acutorostrata*)  
Pilot whale (*Globicephala* spp.)  
Atlantic white-sided dolphin (*Lagenorhynchus acutus*)  
Bottlenose dolphin (*Tursiops truncatus*)  
Common dolphin (*Delphinus delphis*)  
Killer whale (*Orcinus orca*)  
Risso’s dolphin (*Grampus griseus*)  
Harbor porpoise (*Phocoena phocoena*)  
Harbor seal (*Phoca vitulina*)  
Gray seal (*Halichoerus grypus*)

Per the recommendation of the NOAA Fisheries, Northeast Gateway is requesting the authorization for the incidental take by harassment, of small numbers of the same above listed species of marine mammals in Massachusetts Bay that is based on NEG Port operational activities, as was provided by the October 6, 2011 IHA, pursuant to Section 101 (a) (5) of the MMPA and in accordance with 50 CFR § 216 Subpart I.

### **5.1.2 NEG Port Maintenance**

As detailed in section 1.4.1.2, the only NEG Port maintenance activities that would generate underwater noise with sounds exceeding the 120 dB threshold for Level B harassment are those stemming from vessel noises such as turning screws, engine noise, noise of operating machinery, and thruster use during maintenance and repair events. However, the associated noise levels for maintenance and repair would be localized and would not extend beyond the immediate area where construction activities were occurring.

Per the recommendation of the NOAA Fisheries, Northeast Gateway is requesting the authorization for the incidental take by harassment, of small numbers of the same listed species of marine mammals in Massachusetts Bay as described in section 5.1.1, pursuant to Section 101 (a) (5) of the MMPA and in accordance with 50 CFR § 216 Subpart I, in support of maintenance and repair activities.

## **5.2 Algonquin Pipeline Lateral O&M Activities**

As detailed in section 1.4.2, routine inspections of the Algonquin Pipeline Lateral are conducted annually by a ROV launched from a vessel of opportunity. No forms of take are likely or anticipated from this ROV vessel. The only Algonquin Pipeline Lateral maintenance and repair activities that would generate underwater noise with sounds exceeding the 120 dB threshold for Level B harassment are those stemming from vessel noises such as turning screws, engine noise, noise of operating machinery, and thruster use during unplanned maintenance and repair events. However, the associated noise levels for maintenance and repair would be localized and would not extend beyond the immediate area where construction activities were occurring.

The Algonquin Pipeline Lateral is located within the same general waters as the NEG Port and species are expected to be the same as those described for NEG Port activities. Therefore, per the recommendation of the NOAA Fisheries, Algonquin is requesting the authorization for the incidental take by harassment, of small numbers of the same listed species of marine mammals in Massachusetts Bay as described in section 5.1.1, pursuant to Section 101 (a) (5) of the MMPA and in accordance with 50 CFR § 216 Subpart I, in support of maintenance and repair activities.

## **6.0 NUMBERS OF MARINE MAMMAL THAT MIGHT BE TAKEN**

Northeast Gateway and Algonquin seek authorization for potential “taking” of small numbers of marine mammals under the jurisdiction of the NOAA Fisheries in the proposed region of activity. Species for which authorization is sought include the gray seal, harbor seal, harbor porpoise, Atlantic white-sided dolphin, short-beaked common dolphin, bottlenose dolphin, Risso’s dolphin, long-finned pilot whale, killer whale, minke whale, North Atlantic right whale, humpback whale, and fin whale. These 13 species, described in detail in section 4.0, have the highest likelihood of occurring, at least occasionally, in the NEG Port and Algonquin Pipeline Lateral area.

The only anticipated impacts to marine mammals are associated with noise propagation from the use of DP thrusters resulting in short-term displacement of marine mammals from within ensonified zones produced by such noise sources. The O&M activities proposed by Northeast Gateway and Algonquin are not expected to take more than small numbers of marine mammals, or have more than a negligible effect

on their populations based on the seasonal density and distribution of marine mammals, and the vulnerability of these animals to harassment from the frequency of noises.

### **6.1 Basis for Estimating Numbers of Marine Mammals that Might be “Taken by Harassment”**

There are three kinds of noises recognized by NOAA Fisheries: continuous, intermittent, and pulse. No pulse noise activities, such as seismic, blasting, loud sonar, or pile driving, are associated with the operation and maintenance of the NEG Port and Algonquin Pipeline Lateral; thus, the 160/170 dB threshold value does not apply. The noise sources of potential concern are regasification/offloading (continuous) and dynamic positioning of vessels using thrusters (intermittent) during O&M activities. Both continuous and intermittent noise sources carry the 120 dB isopleth threshold.

None of the continuous sound sources associated with the operation of the NEG Port are expected to exceed the 120 dB threshold for Level B harassment. However, the intermittent noise from thruster use associated with dynamic positioning of vessels during the docking with and/or decoupling of the EBRVs from NEG Port facilities may result in the occasional exceedance of the 120 dB threshold for intermittent noise sources. Consequently, EBRV bow thruster use has the potential for take by harassment for any marine mammal occurring within a zone of ensonification (>120 dB) emanating from the sound source. This area, known as the Zone of Influence (ZOI), has a variable maximum radius dependent on water depth and associated differences in transmission loss (see Appendix C).

Underwater noise of critical concern during NEG Port and Algonquin Pipeline Lateral construction would be from vessel noises such as turning screws, engine noise, noise of operating machinery, and thruster use. It is reasonable to assume that a worst-case maintenance and/or repair scenario would result in similar types of activities and require the use of similar support vessels and equipment as used for construction. Consequently, NEG Port and Algonquin Pipeline Lateral maintenance and repair vessel noise has the potential for take by harassment for any marine mammal occurring within a zone of ensonification emanating from the sound source.

The basis for the take estimate is the number of marine mammals that would be exposed to sound levels in excess of 120 dB. Typically this is determined by multiplying the ZOI by local marine mammal density estimates, and then correcting for seasonal use by marine mammals, seasonal duration of noise-generating activities, and estimated duration of individual activities when the maximum noise-generating activities are intermittent or occasional. In the absence of any part of this information, it becomes prudent to take a conservative approach to ensure the potential number of takes is not greatly underestimated.

Based on underwater sound pressure levels and distance to threshold levels during NEG Port and Algonquin Pipeline Lateral operation and maintenance (see Tables 1-3 and 1-4), the worst-case scenarios have been used as the basis for take calculations. Additionally, Northeast Gateway has consistently used a single EBRV for calculating take, as this is the most likely scenario for operational activity at the NEG Port. Overlap between two EBRVs maneuvering at each buoy will occur only 10 percent of the time. EBRV thruster use will only be used intermittently during a 10 to 30 minute period during docking and undocking procedures and therefore the potential for simultaneous, intermittent use of directional thrusters by two EBRVs is not likely during normal operational activities. In the event that such a situation occurs, existing and NOAA Approved-approved mitigations and procedures (e.g., near real-time detections by ABs), coupled with marine mammal observation by designated EBRV lookouts from both vessels would help to avoid and/or minimize any potential harassment to marine mammals in the area.

## **6.1.1 NEG Port**

### **6.1.1.1 NEG Port Operations**

In the NOAA Fisheries October 6, 2011 IHA to Northeast Gateway, the ensonified area at the 120-dB radius was estimated to be 1.6 miles (2.6 kilometers) maximum from the sound source during dynamic positioning for the EBRV, making a maximum ZOI of 8.1 square miles (21.0 square kilometers). The latest calculations, based on empirical received sound pressure levels (see Appendix B and C), estimate the distance of the 120-dB radius to be approximately 2.6 miles (4.3 kilometers), making a maximum ZOI of 21.9 square miles (56.8 square kilometers) for NEG Port operations. This represents a nominal 1 mile (1.7 kilometers) linear difference between modeled estimates originally evaluated in the final EIS/EIR and empirical received sound levels derived from actual field verified measurements taken during EBRV operational activities as used in previous IHA applications. However, it should be noted that despite this increase to the estimated ZOI, to date, based on both ship-board observations and MARU evaluations, no take by harassment has been recorded during NEG Port operations. Furthermore, the mitigation measures currently in place and approved by NOAA Fisheries provide the means of effecting the least practicable adverse impact on marine mammal species or stocks and their habitat.

### **6.1.1.2 NEG Port Maintenance**

Northeast Gateway has analyzed empirical received sound pressure levels collected during specific construction operations as described in section 1.4.1. The latest calculations, based on received sound pressure levels (see Appendix B and C), estimate the distance of the 120-dB radius to be approximately 2.2 miles (3.6 kilometers), making a maximum ZOI of approximately 15.4 square miles (39.8 square kilometers). Originally modeled sound pressure levels, as published in the Federal Register (Vol. 72, No. 48) on March 13, 2007, estimated the distance of the 120-dB radius to be approximately 2 miles (3.31 kilometers) with an associated ZOI of 34 square kilometers. Although the empirical received sound pressure level distance to the 120-dB radius is slightly larger than the originally modeled distances, the results demonstrate consistency between modeled and empirical data. In the case of certain circumstances that require the presence of an EBRV at the NEG Port to support maintenance and repair activities, the ZOI would be larger for EBRV positioning thruster use. In such cases, existing mitigation and estimates on take for EBRV operation are expected to be sufficient.

## **6.1.2 Algonquin Pipeline Lateral O&M Activities**

Algonquin and Northeast Gateway have analyzed empirical received sound pressure levels collected during specific pipeline construction operations as described in section 1.4.2. The latest calculations, based on received sound pressure levels (see Appendix B and C), estimate the distance of the 120-dB radius to be approximately 2.2 miles (3.6 kilometers), making a maximum ZOI of 15.4 square miles (39.8 square kilometers), consistent with NEG Port maintenance and repair activities as stated in section 6.1.1.2. As with NEG Port maintenance and repair activities, the originally modeled sound pressure levels, as published in the Federal Register (Vol. 72, No. 48) on March 13, 2007, estimated the distance of the 120-dB radius to be approximately 2 miles (3.31 kilometers) with an associated ZOI of 34 square kilometers. Although the empirical received sound pressure level distance to the 120-dB radius is slightly larger than the originally modeled distances, the results demonstrate consistency between modeled and empirical data.

## **6.2 Estimate of Numbers of Marine Mammals that Might be “Taken by Harassment”**

On October 20, 2011, NOAA Fisheries also reauthorized the Northeast Gateway Incidental Take Statement (ITS) for the operational period of October 6, 2011 through October 5, 2012. This reauthorization of take was based upon the calculations provided for species in the notice of issuance of the IHA as published in the Federal Register (Vol. 76, No. 196) on October 20, 2011. For consistency, take estimates have been derived utilizing the same estimate methods as provide in the Federal Register (Vol. 76, No. 196) on October 20, 2011, utilizing empirical received sound pressure levels to determine the ensonified area at the 120-dB radius.

### **6.2.1 Estimate of Potential NEG Port Operational Takes by Harassment**

To estimate take for NEG Port operations, estimates of the number of marine mammals that would be exposed to sound levels in excess of 120 dB are determined by multiplying the area of the EBRV's ZOI (56.8 kilometers<sup>2</sup>) by local marine mammal density estimates, and then multiplying by the estimated EBRV visits per year. In the case of data gaps, a conservative approach was used to ensure the potential number of takes is not underestimated.

NOAA Fisheries originally used data on cetacean distribution within Massachusetts Bay, such as those published by the National Centers for Coastal Ocean Science (NCCOS, 2006), to estimate potential takes of marine mammals species in the vicinity of project area. For consistency, these data sources, and NOAA Fisheries Methods for take calculation, have been used to update NEG Port take estimates based on the most recent best available data. The NCCOS study used cetacean sightings from two sources: (1) The North Atlantic Right Whale Consortium (NARWC) sightings database held at the University of Rhode Island (Kenney, 2001); and (2) the Manomet Bird Observatory (MBO) database, held at the NOAA Fisheries, Northeast Fisheries Science Center (NEFSC). The NARWC data contained survey efforts and sightings data from ship and aerial surveys and opportunistic sources between 1970 and 2005. The main data contributors included: Cetacean and Turtles Assessment Program (CETAP), Canadian Department of Fisheries and Oceans, Provincetown Center for Coastal Studies (PCCS), International Fund for Animal Welfare, NOAA's NEFSC, New England Aquarium, WHOI, and the University of Rhode Island. A total of 406,293 miles (653,725 kilometers) of survey track and 34,589 cetacean observations were provisionally selected for the NCCOS study in order to minimize bias from uneven allocation of survey effort in both time and space. The sightings-per-unit-effort (SPUE) was calculated for all cetacean species by month covering the southern Gulf of Maine study area, which also includes the project area (NCCOS, 2006).

The MBO's Cetacean and Seabird Assessment Program (CSAP) was contracted from 1980 to 1988 by NOAA Fisheries NEFSC to provide an assessment of the relative abundance and distribution of cetaceans, seabirds, and marine turtles in the shelf waters of the northeastern United States (MBO, 1987). The CSAP program was designed to be completely compatible with NOAA Fisheries NEFSC databases so that marine mammal data could be compared directly with fisheries data throughout the time series during which both types of information were gathered. A total of 8,383 miles (5,210 kilometers) of survey distance and 636 cetacean observations from the MBO data were included in the NCCOS analysis. Combined valid survey effort for the NCCOS studies included 913,840 miles (567,955 kilometers) of survey track for small cetaceans (dolphins and porpoises) and 1,060,226 miles (658,935 kilometers) for large cetaceans (whales) in the southern Gulf of Maine. The NCCOS study then combined these two data sets by extracting cetacean sighting records, updating database field names to match the NARWC

database, creating geometry to represent survey tracklines and applying a set of data selection criteria designed to minimize uncertainty and bias in the data used.

Owing to the comprehensiveness and total coverage of the NCCOS cetacean distribution and abundance study, NOAA Fisheries has calculated the estimated take number of marine mammals based on the most recent NCCOS report published in December 2006 (see NEG Port IHA 2011, Federal Register [Vol. 76, No. 196]; Neptune LNG Letter of Authorization 2011, Federal Register [Vol. 76, No. 113]). For a detailed description and calculation of the cetacean abundance data and SPUE, please refer to the NCCOS study (NCCOS, 2006). These data show that the relative abundance of North Atlantic right, fin, humpback, minke, sei, and pilot whales, and Atlantic white-sided dolphins for all seasons, as calculated by SPUE in number of animals per square kilometer, is 0.0082, 0.0097, 0.0118, 0.0059, 0.0084, 0.0407, and 0.1314, respectively.

In calculating the area density of these species from these linear density data, NMFS used 0.5 mi (0.825 km) as the hypothetical strip width (W). This strip width is based on the distance of visibility used in the NARWC data that was part of the NCCOS (2006) study. However, those surveys used a strip transect instead of a line transect methodology. Therefore, in order to obtain a strip width, one must divide the visibility or transect value in half. Since the visibility value used in the NARWC data was 2.3 mi (3.7 km), it thus gives a strip width of 1.15 mi (1.85 km). The hypothetical strip width used in the analysis is less than half of that derived from the NARWC data, therefore, the analysis provided here is more protective in calculating marine mammal densities in the area. Based on this information, the area density (D) of these species in the project area can be obtained by the following formula:

$$D = SPUE/2W.$$

Based on this calculation method, the estimated take numbers per year for North Atlantic right, fin, humpback, minke, sei, pilot whales, and Atlantic white-sided dolphins by NEG Port operations, which is an average of 65 visits EBRVS to the Port area per year (or approximately 1.25 visits per week), with vessels' operating thrusters for dynamic positioning before offloading natural gas and before departing from the Port, can be obtained by the following formula:

$$\text{Estimated Take} = D \times ZOI \times (65)$$

The resulting take estimates per year for North Atlantic right, fin, humpback, minke, sei, pilot whales, and Atlantic white sided dolphins by the NEG Port facility operations are 18, 22, 26, 13, 19, 91, and 294 , respectively. These numbers represent a maximum of 4.13, 0.62, 3.21, 0.06, 5.26, 0.72, and 0.60 percent of populations for these species, respectively, based on the latest NMFS Atlantic marine mammal stock assessment reports (Waring et al. 2013). Since it is very likely that individual animals could potentially be “taken” by harassment multiple times, these percentages are the upper boundary of the animal population that could be affected. Therefore, the actual number of individual animals being exposed or taken would be far less. NOAA Fisheries has already determined that there is no danger of injury, death, or hearing impairment from the exposure to these noise levels. In fact, to date, based on both EBRV vessel observations and MARU data, no take by harassment has been recorded during NEG Port operations.

### **6.2.2 Estimate of Potential NEG Port Maintenance and Repair Takes by Harassment**

For NEG Port maintenance/repair, the worst-case scenario, as presented in Table 1-4, has been used as the basis for calculating take using the 120-dB ZOI of approximately 15.7 square miles (40.7 square kilometers). As a conservative measure, and for the sake of consistency, the same data sources and take calculation methods used above for NEG Port operational activities have been used for maintenance and

repair estimates. On June 13, 2011, NOAA Fisheries issued a Letter of Authorization (LOA) to Neptune LNG for the take of marine mammals during both operation and maintenance and repair of the Neptune Port facility. As published in the Federal Register (Vol. 76, No. 113), the NOAA Fisheries determined that the evaluation of a 14-day maintenance period was appropriate for evaluating the potential take associated with a maintenance and repair at the Neptune Port Facility. Due to the fact that both the NEG and Neptune Ports are very similar in their potential need for and type of major and minor maintenance and repair of port facilities, we have applied the same average duration of 14 days to calculate the take for NEG Port maintenance and repair activities.

Based on the same calculation method as described above for NEG Port operations (but using the 120-dB ZOI of approximately 15.7 square miles (40.7 square kilometers)), the estimated take numbers by Level B harassment on an annual basis for North Atlantic right, fin, humpback, minke, sei, and pilot whales, and Atlantic white-sided dolphins incidental to NEG Port maintenance and repair activities, corrected for 50 percent more marine mammals that may be underwater, are 3, 3, 4, 2, 3, 14, and 45, respectively. These numbers are based on 14 days of repair and maintenance activities occurring annually and represent a maximum of 0.64, 0.10, 0.50, 0.01, 0.81, 0.11, and 0.09 percent of populations for these species, respectively. It is unlikely however, that this much repair and maintenance work would be required each year at the Port. In the case of certain circumstances that require the presence of an EBRV at the NEG Port to support maintenance and repair activities, existing mitigation and estimates on take for EBRV operation are expected to be sufficient.

### **6.2.3 Estimate of Potential Algonquin Pipeline Lateral Takes by Harassment**

For Algonquin Pipeline Lateral maintenance and repair activities, the worst-case scenario, as presented in Table 1-4, has been used as the basis for calculating take. As a conservative measure, and for the sake of consistency, the same data sources and take calculation methods used above for NEG Port O&M activities have been used for Algonquin Pipeline Lateral maintenance and repair estimates. Algonquin expects that no more than one repair will be required in any given year. If a DP rather than an anchored vessel is used to complete the repair, thruster use will occur at varying sound levels as necessary for the vessel to hold its position for up to 40 work days, as a worst-case estimate, with operations expected to be occurring up to 24 hours per day 7 days per week. Accordingly, during a repair of the Algonquin Pipeline Lateral, marine mammals could be exposed to sound levels above 120 dB for a maximum period of potential harassment of up to 40 days (up to 960 hours) over the course of one operating year.

Based on the same calculation method as described above for NEG Port operations (but using the 120-dB ZOI of approximately 15.7 square miles (40.7 square kilometers)), the estimated take numbers by Level B harassment on an annual basis for North Atlantic right, fin, humpback, minke, sei, and pilot whales, and Atlantic white-sided dolphins incidental to Algonquin Pipeline Lateral maintenance and repair activities, corrected for 50 percent more marine mammals that may be underwater, are 8, 10, 12, 6, 8, 40, and 130, respectively. These numbers are based on 40 days of repair and maintenance activities occurring annually and represent a maximum of 1.82, 0.27, 1.42, 0.03, 2.32, 0.32, and 0.27 percent of populations for these species, respectively. It is unlikely however, that this much repair and maintenance work would be required each year for the Algonquin Pipeline Lateral.

## **7.0 EFFECTS TO MARINE MAMMAL SPECIES OR STOCKS**

Consideration of negligible impact is required for the NOAA Fisheries to authorize the incidental take of marine mammals. In 50 CFR § 216.103, the NOAA Fisheries defines negligible impact to be “an impact resulting from a specified activity that cannot be reasonably expected to, and is not reasonably likely to,

adversely affect the species or stocks [of marine mammals] through effects on annual rates of recruitment or survival.” Based upon best available data regarding the marine mammal species (including density, status, and distribution) that are likely to occur in the NEG Port and Algonquin Pipeline Lateral area as well as in-field acoustic assessment surveys of NEG Port activities, Northeast Gateway and Algonquin Pipeline conclude that exposure to marine mammal species and stocks due to NEG Port and Algonquin Pipeline Lateral operations would result in short-term minimal effects and would not likely affect the overall annual recruitment or survival for the following reasons:

- As evidenced in section 1.4 and Appendices B and C, potential acoustic exposures from NEG Port and Algonquin Pipeline Lateral activities are within the non-injurious behavioral effects zone (Level B harassment);
- The potential for take as estimated in section 6.2 represent conservative estimates of harassment based upon worst-case operating and maintenance/repair scenarios without taking into consideration the effects of standard mitigation and monitoring measures; and
- The protective measures as described in sections 11.0 and 13.0 and Appendix A are designed to minimize the potential for interactions with and exposure to marine mammals.

## **8.0 MINIMIZATION OF ADVERSE EFFECTS TO SUBSISTENCE USES**

There are no traditional subsistence hunting areas in the NEG Port or Algonquin Pipeline Lateral area.

## **9.0 EFFECTS TO MARINE MAMMALS FROM LOSS OR MODIFICATION OF HABITAT AND THE LIKELIHOOD OF RESTORATION**

NEG Port and Algonquin Pipeline Lateral operations are not likely to change over the next year. The USCG has requested an Environmental Impact Assessment (EIA) regarding water usage levels at the Port. Effects to marine mammals from loss or modification of habitat, updated to include the requested water use scenario for the NEG Port, are discussed in the following sections.

### **9.1 NEG Port Operations**

Operation of the NEG Port will not result in short-term effects; however, long-term effects on the marine environment, including alteration of the seafloor conditions, continued disturbance of the seafloor, regular withdrawal of sea water, and regular generation of underwater noise, will result from Port operations. Specifically, a small area (0.14 acre) along the Pipeline Lateral has been permanently altered (armored) at two cable crossings. In addition, the structures associated with the NEG Port (flowlines, mooring wire rope and chain, suction anchors, and pipeline end manifolds) occupy 4.8 acres of seafloor. An additional area of the seafloor of up to 43 acres (worst case scenario based on severe 100-year storm with EBRVs occupying both STL buoys) will be subject to disturbance due to chain sweep while the buoys are occupied.

EBRVs are currently authorized to withdraw an average of 4.97 million gallons per day (mgd) and 2.6 billion gallons per year of sea water for general ship operations during its cargo delivery activities at the NEG Port. However, on December 10, 2012, the MARAD and USCG issued a final EIA regarding Northeast Gateway’s requested changes for water use including

- 11 billion gallons of total annual water use at the Port;
- Maximum daily intake volume of up to 56 million gallons per day (mgd) at a rate of 0.45 feet per second when an EBRV is not able to achieve the HRS mode of operation; and,

- Maximum daily change in discharge temperature of 12°C (21.6°F) from ambient from the vessel's main condenser cooling system.

Under the requested water-use scenario, the estimated annual loss of 3,000 kilograms of phytoplankton biomass per year (8.2 kilograms per day) will result in the estimated loss of about 300 kilograms per year (0.8 kilograms per day) of zooplankton, and 30 kilograms per year (0.08 kilograms per day) of small planktivorous fish such as Atlantic herring. Loss of zooplankton biomass is about 1,500 kilograms per year (4.1 kilograms per day), resulting in loss of about 150 kilograms per year (0.4 kilograms per day) of planktivorous fish. The loss of zooplankton represents a direct impact to whales and the trophic transfer to planktivorous fish represents an indirect impact; however, these losses are minor relative to the total biomass of these trophic levels in Massachusetts Bay. Additionally, the estimated losses of ichthyoplankton are not significant given the very high natural mortality of ichthyoplankton.

The results of a prey consumption model based on the requested water-use scenario of 56 mgd have been presented in the USCG EIA. Estimates of daily consumption by a single whale range from 400 kilograms for a sei whale to 1 metric ton for a fin whale using a higher body weight estimate. Annual consumption estimates for a single whale range from 25 to 244 metric tons, and annual consumption estimates for the entire Massachusetts Bay or northeastern U.S. populations range upward to tens or hundreds of thousands of metric tons. Those rates dwarf any reasonable estimates of prey removals by NEG Port operations, which therefore must be considered as negligible.

Consideration has also been given to the long-term consequences of NEG Port operation on prey removal for whales and the downstream effects this removal could have on the distribution of prey items outside of the project area. As the Maine Coastal Current passes through the NEG Port area, prey items are carried downstream and distributed to known foraging grounds of whales in Massachusetts Bay and Cape Cod Bay and Stellwagen Bank. Even if the daily transport rates for the Maine Coastal Current vary by an order of magnitude above and below the average, the proportion of the flow withdrawn would still be a fraction of one percent at the lowest current flows. The interannual variability in abundance of each of the primary prey stocks for endangered whales in the region—large copepods, sand lance, and herring—are all much more than a few percent, therefore the short- and long-term impacts of removals would be undetectable against normal variability.

None of the prey-related distributional shifts analyzed in the USCG EIA resulted in any detectable change in mortality rates of whale stocks. In only one case has a potential impact of variability in prey resources on life-history parameters of a whale population in the western North Atlantic been identified. Greene et al. (2003) correlated patterns in the North Atlantic Oscillation Index, an index of slope water temperature for the Gulf of Maine region, a normalized index of *C. finmarchicus* abundance across the entire Gulf of Maine, and the numbers of calves born each year in the western North Atlantic right whale stock. The working hypothesis is that low copepod densities across most or all of the feeding range of the right whales, while not sufficiently low to increase mortality (i.e., cause starvation), may be insufficient to support increased feeding rates by adult females that are trying to recover blubber-lipid stores between calves (Greene et al. 2003; Greene and Pershing 2004; Kenney 2007). The effect would be to increase the resting time between calves and the inter-birth interval, as was observed during the 1990s (Kraus et al. 2001).

If background variability in prey abundance is orders of magnitude greater than changes that might potentially be caused by NEG Port operations, and if substantial variability in prey resources across the

entire Gulf of Maine area causes only variation in calving intervals of one of the whale species, any small effect of NEG Port operations on whale distributions or demographics cannot possibly be detectable.

Approximately 4.8 acres of seafloor has been converted from soft substrate to the artificial hard substrate of the structures associated with the NEG Port. An additional area of up to 38 acres is subject to disturbance due to chain sweep while the buoys are occupied by the EBRVs. Given the relatively small size of the NEG Port area that will be directly affected by Port operations (see section 1.2), Northeast Gateway does not anticipate that habitat loss will be significant. In addition, the possible removal benthic or planktonic species, resulting from the relatively minor EBRV water use requirements while at port, is unlikely to affect in a measurable way the food sources available to marine mammals. At the end of the useful life of the NEG Port (approximately 40 years), the Port facilities will be removed and or abandoned in place, in compliance with all applicable and appropriate regulations, guidelines, and technologies in place at that time to ensure habitat integrity.

## **9.2 NEG Port Maintenance**

As stated in section 1.3.2, the NEG Port will require scheduled maintenance inspections using either divers or ROVs. The duration of these inspections are not anticipated to be more than two 8-hour working days. An EBRV will not be required to support these annual inspections. Air emissions would be limited to the diver/ROV support vessel. Emissions associated with these vessels have been previously calculated and evaluated in the Massachusetts Conformity Determination during the licensing of the Project (Section A.2, p. 18).

Water usage would be limited to the standard requirements of NEG's normal support vessel. As with all vessels operating in Massachusetts Bay, sea water uptake and discharge is required to support engine cooling, typically using a once-through system. The rate of seawater uptake varies with the ship's horsepower and activity and therefore will differ between vessels and activity type. For example, the Gateway Endeavor is a 90-foot vessel powered with a 1,200 horsepower diesel engine with a four-pump seawater cooling system. This system requires seawater intake of about 68 gallons per minute (gpm) while idling and up to about 150 gpm at full power. Use of full power is required generally for transit. A conservatively high estimate of vessel activity for the Gateway Endeavor would be operation at idle for 75 percent of the time and full power for 25 percent of the time. During the routine activities this would equate to approximately 42,480 gallons of seawater per 8-hour work day. When compared to the engine cooling requirements of an EBRV over an 8-hour period (approximately 18 million gallons), the Gateway Endeavour uses about 0.2 percent of the EBRV requirement. To put this water use into context, potential effects from the waters-use scenario of 56 mgd have been concluded to be orders of magnitude less than the natural fluctuations of Massachusetts Bay and Cape Cod Bay and not detectable. Water use by support vessels during routine port activities would not materially add to the overall impacts. Additionally, discharges associated with the Gateway Endeavor and/or other support/maintenance vessels that are 79 feet or greater in length, are now regulated under the Clean Water Act (CWA) and must receive and comply with the United States Environmental Protection Agency (EPA) Vessel General Permit (VGP). The permit incorporates the USCG mandatory ballast water management and exchange standards, and provides technology- and water quality-based effluent limits for other types of discharges, including deck runoff, bilge water, graywater, and other pollutants. It also establishes specific corrective actions, inspection and monitoring requirements, and recordkeeping and reporting requirements for each vessel.

Certain maintenance and repair activities may also require the presence of an EBRV at the Port. Such instances may include maintenance and repair on the STL Buoy, vessel commissioning, and any onboard

equipment malfunction or failure occurring while a vessel is present for cargo delivery. Because the requested water-use scenario allows for daily water use of up to 56 mgd (see section 9.1) to support standard EBRV requirements when not operating in the HRS mode, vessels will be able to remain at the Port as necessary to support all such maintenance and repair scenarios. This minimizes the need for frequent transit to and from the Port and the use of thrusters to support mooring and unmooring activities, thereby minimizing, proportionally, the potential for vessel strike and acoustic harassment of marine mammals and sea turtles from Port activities.

### **9.3 Unanticipated Algonquin Pipeline Lateral Maintenance and Repair**

As stated in section 1.3.3, proper care and maintenance of the Algonquin Pipeline Lateral should minimize the likelihood of an unanticipated maintenance and/or repair event; however, unanticipated activities may occur from time to time if facility components become damaged or malfunction. Unanticipated repairs may range from relatively minor activities requiring minimal equipment and one or two diver/ROV support vessels to major activities requiring larger construction-type vessels similar to those used to support the construction and installation of the facility. Air emissions would be limited, ranging from a diver/ROV support vessel to construction-type vessels. Emissions associated with these vessels have been previously calculated and evaluated in the Massachusetts Conformity Determination during the licensing of the Project (Section A.2, p. 18).

Major repair activities, although unlikely, may include repairing or replacement of pipeline manifolds or a sections of the Pipeline Lateral. This type of work would likely require the use of large specialty construction vessels such as those used during the construction and installation of the NEG Port and Algonquin Pipeline Lateral. The duration of a major unplanned activity would depend upon the type of repair work involved and would require careful planning and coordination.

Turbidity would likely be a potential effect of Algonquin Pipeline Lateral maintenance and repair activities on listed species. In addition, the possible removal benthic or planktonic species, resulting from relatively minor construction vessel water use requirements, as measured in comparison to EBRV water use, is unlikely to affect in a measurable way the food sources available to marine mammals. Discharges associated with maintenance and repair vessels that are 79 feet or greater in length, are now regulated under the CWA and must receive and comply with the EPA VGP. The permit incorporates the USCG mandatory ballast water management and exchange standards, and provides technology- and water quality-based effluent limits for other types of discharges, including deck runoff, bilge water, graywater, and other pollutants. It also establishes specific corrective actions, inspection and monitoring requirements, and recordkeeping and reporting requirements for each vessel.

At the end of its useful life (approximately 40 years), the Algonquin Pipeline Lateral will be removed and or abandoned in place, in compliance with all applicable and appropriate regulations, guidelines, and technologies in place at that time to ensure habitat integrity.

## **10.0 THE EFFECTS OF HABITAT LOSS OR MODIFICATION ON MARINE MAMMALS**

As stated above, approximately 4.8 acres of seafloor has been converted from soft substrate to artificial hard substrate. The soft-bottom benthic community may be replaced with organisms associated with naturally occurring hard substrate, such as sponges, hydroids, bryozoans, and associated species. The benthic community in the up to 43 acres (worst case scenario based on severe 100-year storm with EBRVs occupying both STL buoys) of soft bottom that may be swept by the anchor chains while EBRVs

are docked will have limited opportunity to recover, so this area will experience a long-term reduction in benthic productivity. In addition, disturbance from anchor chain movement would result in increased turbidity levels in the vicinity of the buoys that could affect prey species for marine mammals; however, as indicated in the final EIS/FEIR, these impacts are expected to be short-term, indirect, and minor.

Daily removal of sea water from EBRV intakes will reduce the food resources available for planktivorous organisms. Massachusetts Bay circulation will not be altered, however, so plankton will be continuously transported into the NEG Port area. The removal of these species is minor and unlikely to affect in a measurable way the food sources available to marine mammals.

As discussed in section 9.2, planned maintenance activities at the NEG Port will result in sea water intakes and therefore removal of planktivorous organisms. The removal of these species is minor and unlikely to affect in a measurable way the food sources available to marine mammals.

Maintenance and repair activities for the Algonquin Pipeline Lateral, as discussed in section 9.3, will result in increased levels of turbidity which can interfere with the ability of whales to forage effectively by obscuring visual detection of or dispersing potential prey. Disturbance of the seafloor through jetting, laybarge anchoring, and other repair activities can also release contaminated sediments back into the water column, thus exposing marine organisms to contaminants that were previously attached to sediment particles. Although increased turbidity may cause displacement of whales or their prey, displacement will be temporary, and whales are likely to find suitable prey in surrounding areas. Additionally, any possible removal benthic or planktonic species, resulting from relatively minor construction vessel water use requirements, as measured in comparison to EBRV water use, is unlikely to affect in a measurable way the food sources available to marine mammals.

## **11.0 MEANS OF AFFECTING THE LEAST PRACTICABLE IMPACT UPON EFFECTED SPECIES OR STOCKS**

Northeast Gateway and Algonquin have committed to a comprehensive set of mitigation measures during operation as well as on-going consultations with NOAA Fisheries. These measures include:

- Passive acoustics program
- Visual monitoring program
- Safety zones
- Reporting
- Vessel speed restrictions
- Ramp-up procedures

To date, these mitigation and monitoring activities have successfully safeguarded marine mammals and sea turtles, resulting in a total of only 1 take by acoustic harassment over the past 3 years of operation. This number is well within the yearly permitted number of level B harassment takes for operational activities listed in the current IHA (as issued on October 6, 2011) and ITS (as issued on October 20, 2011) of 5 right, 5 fin, and 15 humpback whales. With these mitigation in place, NEG Port and Algonquin Pipeline Lateral O&M activities will likely result in no change to underwater noise impacts from those evaluated and currently mitigated for per the requirements of Northeast Gateway's permits. However, to ensure the continued protection of marine mammals and sea turtles in the NEG Port and Algonquin Pipeline Lateral area during all maintenance and repair events, Northeast Gateway has provided a revised Prevention, Monitoring and Mitigation Program (PMMP) and a revised MMDMRP as Appendix A and I,

respectively. The revised PMMP and MMDMRP adapt the approved strategies for minimizing and avoiding impacts to marine resources developed for construction to minimize/avoid impact during potential future maintenance and repair activities, including the use of DP vessels. Monitoring and reporting for these activities is discussed in further detail in section 13.0.

## **12.0 THE EFFECTS OF NEG PORT ACTIVITIES ON SPECIES OR STOCK OF MARINE MAMMALS AVAILABLE FOR ARCTIC SUBSISTENCE USES**

Potential impacts to species or stocks of marine mammals will be limited to individuals of marine mammal species located of the Northeast Region of the United States, and will not affect Arctic marine mammals. Given that the NEG Port is not located in Arctic waters, the activities associated with the NEG Port will not have an adverse affect on the availability of marine mammals for subsistence uses allowable under the MMPA. It is Northeast Gateway's intent to apply for an IHA to be issued for NEG Port operational activities, as was provided by the August 27, 2010 IHA. This is consistent with the direction of NOAA Fisheries provided on January 25, 2010 via personal communication with Shane Guan.

## **13.0 MONITORING AND REPORTING**

Northeast Gateway shall monitor the noise environment in Massachusetts Bay in the vicinity of the NEG Port and Algonquin Pipeline Lateral using an array of 19 Marine Autonomous Recording Units (MARUs) that were deployed initially in April 2007 to collect data during the preconstruction and active construction phases of the NEG Port and Algonquin Pipeline Lateral. A description of the MARUs can be found in Appendix A of this application. These 19 MARUs shall remain in the same configuration for a period of five years during full operation of the NEG Port and Algonquin Pipeline Lateral. The MARUs collect archival noise data and are not designed to provide real-time or near-real-time information about vocalizing whales. Rather, the acoustic data collected by the MARUs shall be analyzed to document the seasonal occurrences and overall distributions of whales (primarily fin, humpback, and right whales) within approximately 10 nautical miles of the NEG Port, and shall measure and document the noise "budget" of Massachusetts Bay so as to eventually assist in determining whether an overall increase in noise in the Bay associated with the NEG Port and Algonquin Pipeline Lateral might be having a potentially negative impact on marine mammals. The overall intent of this system is to provide better information for both regulators and the general public regarding the acoustic footprint associated with long-term operation of the NEG Port and Algonquin Pipeline Lateral in Massachusetts Bay, and the distribution of vocalizing marine mammals during NEG Port activities (analyzed to assess impacts of former on latter). In addition to the 19 MARUs, Northeast Gateway shall deploy 10 Auto-Detection Buoys (ABs) within the TSS for the operational life of the NEG Port. A description of the ABs can be found in Appendix A of this application. The purpose of the ABs shall be to detect a calling North Atlantic right whale an average of 5 nautical miles from each AB (detection ranges will vary based on ambient underwater conditions). The AB system shall be the primary detection mechanism that alerts the EBRV Master and/or NEG Port and Algonquin Pipeline Lateral support vessel captains to the occurrence of right whales, heightens EBRV or NEG Port and Algonquin support vessel awareness, and triggers necessary mitigation actions as described in the PMMP included as Appendix I of this application.

Northeast Gateway has engaged representatives from Cornell University's BRP and the WHOI as the consultants for developing, implementing, collecting, and analyzing the acoustic data; reporting; and maintaining the acoustic monitoring system.

Further information detailing the deployment and operation of arrays of 19 passive seafloor acoustic recording units (MARUs) centered on the terminal site and the 10 ABs that are to be placed at approximately 5-mile intervals within the recently modified TSS can be found in the MMDMRP included as Appendix A of this application.

#### **14.0 RESEARCH**

Ongoing research for Northeast Gateway is associated with monitoring the noise environment in Massachusetts Bay in the vicinity of the NEG Port using an array of 19 MARUs that were deployed initially in April 2007.

Because operations at the Port are not changing and at the direction of NOAA Fisheries, the IHA Application was developed to closely follow the application submitted on January 26, 2009 and approved by NOAA Fisheries on August 28, 2009. Cornell University's BRP and the Woods Hole Oceanographic Institution (WHOI) worked closely with Northeast Gateway to develop and implement the acoustic monitoring program. BRP and WHOI are also responsible for collecting and analyzing the acoustic data, reporting, and maintaining the acoustic monitoring system. BRPs 2009 Operational was submitted on February 8, 2011. The final reports from BRP for 2010 and 2011 are pending and will be provided to agencies.

Further information regarding the deployment and operation of the MARU array and the 10 Auto-Detection Buoys (ABs) is detailed in section 13 of this application and in the MMDMRP included as Appendix A of this application.
